Final Environmental Impact Statement / Final Environmental Impact Report

South Coast Rail Project

Bristol, Plymouth, Norfolk and Suffolk Counties
Commonwealth of Massachusetts

Department of the Army Permit Application Number NAE–2007–00698
Executive Office of Energy and Environmental Affairs EEA No. 14346

Lead Federal Agency:	U.S. Army Corps of Engineers, New England District, Regulatory Division 696 Virginia Road, Concord, MA 01742-2751
Cooperating Agencies:	U.S. Environmental Protection Agency Federal Transit Administration Federal Highway Administration Federal Railroad Administration

Abstract: This Final Environmental Impact Statement (FEIS) was prepared pursuant to section 102(2) (c) of the National Environmental Policy Act (NEPA) of 1969, as implemented by the Council on Environmental Quality regulations (40 CFR parts 1500-1508), and U.S. Army Corps of Engineers Regulations (Appendix B to 33 CFR part 325). This FEIS was prepared to assist in review of a Department of the Army Permit application submitted on May 8, 2008 by the Massachusetts Executive Office of Transportation and Public Works (currently known as the Massachusetts Department of Transportation, or MassDOT) under Section 404 of the Clean Water Act and potentially Section 10 of the Rivers and Harbors Act of 1899. The permit application was submitted for the discharge of fill material into waters of the United States (U.S.), ranging in area from less than eleven acres to approximately twenty-one acres (depending on the alternative selected), including wetlands, incidental to the construction of new public passenger rail (or other public transportation) facilities connecting the terminal stations of Fall River and New Bedford with South Station in Boston, Massachusetts (the Project). A "Notice of Intent" to prepare an Environmental Impact Statement on this permit application was published in the Federal Register on October 31, 2008.[1] Notices of Availability of the Draft Environmental Impact Statement (DEIS) were published in the Federal Register on March 25, 2011,[2] and April 1, 2011.[3]

The Massachusetts Department of Transportation (MassDOT) considered several transportation facilities and corridor alternatives to implement the proposed transit service over a distance of approximately 50 to 60 miles. Transportation modes considered included rail (diesel or electric) and rapid bus. Corridors considered included a rail corridor through Attleboro, Stoughton or Middleborough or a rapid bus service along the Route 24 corridor. MassDOT's preferred alternative is the Stoughton commuter rail alternative (using electric or diesel powered locomotives) which involves using the active freight rail lines from New Bedford and Fall River to Taunton, then using the inactive rail bed north to Stoughton, then using the active commuter rail tracks to South Station in Boston.

---

[1] Federal Register 73:212, 64927-64928 (October 31, 2008)
[2] Federal Register 76:58, 16737 -16739 (March 25, 2011)
[3] Federal Register 76:63, 18218 (April 1, 2011; EIS No. 20110095)

The U.S. Army Corps of Engineers has determined that there is no practicable alternative to the Stoughton Electric alternative which would have less adverse impact on the aquatic ecosystem, and also does not have other significant adverse environmental consequences.

This document was prepared with the intent to serve as a Massachusetts Environmental Policy Act (MEPA) and NEPA document to comply with the procedural requirements of both state and federal law and serve as a combined Final Environmental Impact Statement (FEIS)/Final Environmental Impact Report (FEIR). The State's environmental review pursuant to the Massachusetts Environmental Policy Act (MEPA) (G. L. c. 30, ss. 61-621) and the MEPA regulations (301 CMR 11.00) is being conducted simultaneously with the NEPA process.

This FEIS/FEIR compares the direct, indirect and cumulative impacts of the alternatives on the natural, cultural and socioeconomic environment, including vernal pools and other wetlands; cultural resources; threatened and endangered species; transportation; air quality, including greenhouse gas emissions; noise and vibration; surface water and groundwater; hydrology and water quality; and socioeconomic effects. Mitigation is proposed to offset or reduce the unavoidable impacts of the alternatives. The FEIS/FEIR also provides responses to the public and agency comments received on the DEIS/DEIR, updated technical analyses conducted subsequent to the DEIS/DEIR, and the compliance of the alternatives with various state and federal environmental regulations.

A public notice announcing the availability of this document will be published concurrently with an announcement in the Federal Register. Copies of this FEIS/FEIR are available at repositories that are listed on the public notice. Under NEPA regulations, the U.S. Army Corps of Engineers must wait a minimum of 30 days following release of this FEIS/FEIR before it can complete its Record of Decision (ROD) on the applicant's proposed action. The ROD on whether to issue or deny a Department of the Army permit will likely take several months to complete after the FEIS.

P0 PREFACE TO THE FEIR

This preface has been prepared by the Massachusetts Department of Transportation (MassDOT), which is solely responsible for its content. The preface documents MassDOT's compliance with the Massachusetts Environmental Policy Act (MEPA), provides a summary of the environmental review process for the South Coast Rail project, summarizes MassDOT's civic and agency involvement process, and identifies MassDOT's Preferred Alternative. Section P7 of this Preface summarizes the requirements of the Certificate issued by the Secretary of the Executive Office of Energy and Environmental Affairs (EEA) on the Draft Environmental Impact Report (DEIR) and how the Final Environmental Impact Statement/Environmental Impact Report (FEIS/FEIR) addresses each specific requirement.

P1 BACKGROUND

The South Coast Rail project is an initiative of MassDOT and the Massachusetts Bay Transportation Authority (MBTA) to bring public transportation to the South Coast region that will increase access to transit for an underserved area of the state, increase transit ridership, improve regional air quality, reduce greenhouse gas emissions, and support opportunities for smart growth and economic development.

This project is a priority transportation initiative for the Commonwealth of Massachusetts by the Patrick Administration, as documented in the April 2007 South Coast Rail: A Plan for Action and January 2013 The Way Forward: a 21st Century Transportation Plan.

Prior to 1958, the Middleborough, Stoughton, and Attleboro rail lines were part of the Old Colony Railroad System that provided service to Fall River and New Bedford from Boston's South Station, via Canton Junction, along the Stoughton Branch railroad. Since discontinuation of this service, commuter rail has only been available to southeastern Massachusetts along the Boston-Providence Shore Line, with stops in Attleboro and South Attleboro, and the Old Colony Middleborough Line, which terminates in Lakeville. However, none of these provide an opportunity for commuters from the Fall River or New Bedford areas to easily or efficiently access rail transportation to Boston.

The South Coast Rail project, to restore passenger rail service to the South Coast region, has been extensively studied in different configurations for almost 20 years. In 2002, a FEIR, prepared by the MBTA, concluded that the Stoughton Alternative was the most practicable and feasible of the alternatives and identified it as the preferred route. On August 30, 2002, the MEPA Secretary of Environmental Affairs issued a Final Certificate (Executive Office of Environmental Affairs [EOEA] File # 10509) stating that the FEIR adequately and properly complied with MEPA and its implementing regulations. The Certificate authorized MassDOT to proceed with planning for the South Coast Rail project as an extension of the existing Stoughton Line. However, further planning was delayed until 2007.

Section 404 of the Clean Water Act requires a Department of the Army permit for the discharge of dredged or fill material in waters of the United States. Accordingly, for the project to proceed to construction it is necessary for MassDOT to obtain a Section 404 permit from the U.S. Army Corps of Engineers (the Corps) and for the Corps to conduct a federal environmental review in accordance with the National Environmental Policy Act (NEPA).

The Commonwealth recognizes that the final determination of a recommended alternative must occur through a combined state and federal environmental review. Therefore, beginning in 2007 the Patrick-Murray Administration took a fresh look at the alternatives through a transparent and comprehensive evaluation.

The Corps and MEPA have agreed to coordinate the environmental review for the project. The Corps, the lead federal agency for the environmental review pursuant to NEPA, has prepared this federal Environmental Impact Statement (EIS), which MassDOT has reviewed and adopted as its state-required Environmental Impact Report (EIR).

The coordinated environmental review process began with a joint federal/state scoping process. MassDOT, as the lead state agency, submitted an Environmental Notification Form (ENF) to the Executive Office of EEA on November 15, 2008 for public review under MEPA, concurrent with the Corps' public scoping process under NEPA. The Secretary of the Executive Office of EEA issued a Certificate on the ENF, and a Scope for the Draft EIR, on April 3, 2009. A Draft EIR was filed with the MEPA Office on March 15, 2011 and the Secretary issued a Certificate on the DEIR, and a Scope for the Final EIR, on June 29, 2011. This Final EIR meets the requirements established in the Certificate, as described in detail in this Preface and the Response to Comments section of the FEIS/FEIR (Volume III).

P2 PROJECT GOALS

The purpose of the South Coast Rail project is to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts, to enhance regional mobility, while supporting smart growth planning and development strategies in affected communities.

The Corps, for purposes of Section 404 review, has adopted a modification of this statement as its "overall project purpose": The purpose of the South Coast Rail project is to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts to enhance regional mobility. MassDOT believes that the two purpose statements are consistent, and recognizes that the Corps will not consider the relative ability of the DEIS/DEIR alternatives to support smart growth planning in its determination of the Least Environmentally Damaging Practicable Alternative (LEDPA).

P3 CIVIC AND AGENCY INVOLVEMENT

To ensure effective and inclusive outreach to stakeholders throughout the various stages of project development, MassDOT has implemented a comprehensive community involvement process for the South Coast Rail project that included an Interagency Coordinating Group, the Southeastern Massachusetts Commuter Rail Task Force (Commuter Rail Task Force), and an extensive civic engagement process. This section reports on civic engagement since the publication of the DEIS/DEIR.

P3.1 COMMUTER RAIL TASK FORCE

The MEPA process that concluded in 2002 recognized the induced growth that could result from the project and called for a growth management task force to be created. In 2004, the Commuter Rail Task Force was formed to help the region prepare for the impacts of the re-introduction of passenger rail to the South Coast. Its membership includes representatives from the MBTA, regional transit authorities, cities and towns, environmental groups, and business and economic development organizations.

Currently, the group is staffed by the Southeastern Regional Planning and Economic Development District (SRPEDD) and chaired by Interim Chair Susan Peterson Teal.

The Commuter Rail Task Force provides a forum for state officials and local representatives to review and discuss all aspects of the project and to work toward consensus on strategies and actions to plan ahead for new growth in the region. The Task Force provides advice and assistance to MassDOT and the MBTA in the design of the project and in the implementation of the South Coast Rail Economic Development and Land Use Corridor Plan.

P3.2 CIVIC ENGAGEMENT SINCE THE DEIS/DEIR

MassDOT and the MBTA have continued the robust civic engagement process to help better design the project and address the concerns of the region's residents. Outreach includes community meetings with corridor municipalities, briefings for area legislators, large civic engagement meetings for members of the public, and small focused meetings on particular aspects of the project that are of interest to individuals and community groups throughout the corridor.

During preparation of the FEIS/FEIR, MassDOT has focused on civic engagement associated with the proposed commuter rail stations and layover facilities. This outreach has included an Open House in New Bedford, an Open House in Fall River as well as presentations to the city councils and community groups.

MassDOT maintains a project website (http://www.mass.gov/southcoastrail) to provide updated project information such as news releases, fact sheets, materials from the civic engagement meetings, Interagency Coordinating Group meeting materials and minutes, and past environmental reports. The website is updated regularly.

Aside from the project website, interested parties, elected officials, and residents are notified of upcoming meetings and new information through fact sheets, newspaper announcements, flyers and posters, cable-televised meetings, and/or e-mail notifications.

P3.3 CIVIC ENGAGEMENT FOR THIS FEIS/FEIR

MassDOT is committed to ensuring comprehensive public awareness and understanding of this complex environmental document so the public and other interested parties can provide informed comments on substantive environmental issues to MEPA and the Corps. MassDOT has published a "Readers' Guide to the FEIS/FEIR" and a Fact Sheet that summarizes MassDOT's understanding of this document's main findings. These documents are available on the project website, www.mass.gov/southcoastrail. Information on public meetings will be posted on the website as well as through the local media and through the project's e-mail list. To sign up for e-mail notifications, please send an email to: jean.fox@state.ma.us.

P4 MASSDOT'S PREFERRED ALTERNATIVE

The MEPA regulations (301 CMR 11.00) and procedures require that the proponent provide a detailed analysis of "the project" in the DEIR, as well as an analysis of alternatives to the project. The intent of these regulations is for the FEIR to provide sufficient information on the project to allow state agencies to make decisions on their actions (funding and environmental permits).

MassDOT has identified the Stoughton family of alternatives as the Commonwealth's preferred corridor for the South Coast Rail project. The FEIS/FEIR presents an evaluation of the environmental consequences of four alternatives (Stoughton Diesel, Stoughton Electric, Whittenton Diesel, and Whittenton Electric) to support the Corps' decision-making process consistent with the Section 404(b)(1) guidelines.

MassDOT has chosen to identify a preferred corridor in the state portion of this FEIS/FEIR to facilitate review of the South Coast Rail project under MEPA. The Stoughton Alternatives (electric and diesel modes) would extend existing Stoughton Line commuter rail service to Fall River and New Bedford using existing commuter rail lines to Stoughton Station, restored commuter rail lines from Stoughton Station to Taunton, and existing freight rail lines from Taunton to Fall River and to New Bedford. These alternatives meet the project purpose of more fully meeting the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts, to enhance regional mobility, while supporting smart growth planning and development strategies in affected communities. MassDOT believes this family of alternatives best balances transportation and environmental benefits with environmental impacts.

MassDOT understands that there are many environmental concerns about the Stoughton Alternatives, particularly because this corridor crosses the Hockomock Swamp Area of Critical Environmental Concern (ACEC) on a historic railroad bed. MassDOT has carefully studied these environmental issues and has incorporated a trestle into the design to minimize impacts to wetlands and wildlife. The analysis indicates that the Stoughton Alternatives are permittable. Adequate mitigation will need to be provided, particularly for impacts to wetlands, wildlife habitat, rare species and water quality. Although the Stoughton corridor would have environmental impacts, it provides the greatest transportation benefits and—unlike the other corridors—fully meets the project purpose.

Although the Secretary's Certificate stated that MassDOT had made the case for the Stoughton Route to be the preferred alternative in the FEIR, and further stated that, because the electric option is preferable from an air quality perspective, the Stoughton Electric should be the focus of the FEIR, MassDOT has not identified a preferred mode for the Stoughton Alternatives. Although the electric mode provides more transportation benefit and has substantial transportation, air quality, and climate benefits, it would have greater visual impacts and impacts to historic resources and would be substantially more expensive to construct.

MassDOT believes that the Stoughton Alternative would have greater benefits to the South Coast Rail communities, greater benefits with respect to air quality, and fewer noise impacts (particularly to environmental justice communities) than the Whittenton Alternative. Although the Whittenton Alternative would have slightly less impact to aquatic resources, it would have greater adverse impacts to the upland habitat of state-listed species and to ecological integrity and would have more adverse effects to archaeological resources. The comparison of impacts shows that the Whittenton Alternative would have greater adverse environmental consequences which, if balanced against the small difference in the impacts to aquatic resources, would have more adverse environmental consequences than the Stoughton Alternative.

P5 CHANGES SINCE THE DEIS/DEIR

Several elements of the South Coast Rail project have been advanced since the publication of the DEIS/DEIR, in order to better characterize the project impacts and mitigation measures. These changes are fully described in Chapter 3 of the FEIS/FEIR.

- The design of the track, stations, and layover facilities has been advanced to better address the project's impacts on wetlands and natural resources.
- Wetlands throughout the project corridor were field-delineated, reviewed and approved by the Conservation Commissions or DEP.
- The operating plan was refined to optimize train performance and ridership. New ridership estimates were calculated.
- The overnight layover facility locations were selected as the Wamsutta site in New Bedford and the Weaver's Cove East site in Fall River.
- The proposed Stoughton Station was shifted to the south, with access from Brock Street.
- The proposed Downtown Taunton Station (for the Whittenton Alternative) was shifted north, to a location on Dana Street.

P6 SMART GROWTH EVALUATION PLAN

MassDOT has retained the smart growth language in the Commonwealth's project purpose because transportation and land use planning need to be integrated in order to achieve the full benefits of the investment and to spur sustainable development. Conversely, transportation infrastructure which encourages economic and housing growth is likely to result in uncontrolled growth (sprawl) if not combined with smart growth planning and strategies.

Smart growth means concentrating development in places that are already served by infrastructure and preserving natural areas and their resources. Smart growth development is typically compact, transit-oriented, walkable, and bicycle-friendly, and can include neighborhood schools, complete streets, and mixed-use development with a range of housing choices. Smart growth values long-range, regional sustainability over short-term benefits. Its goals are to achieve a unique sense of community and place; expand the range of transportation, employment, and housing choices; equitably distribute the costs and benefits of development; preserve and enhance natural and cultural resources; and promote public health.

To manage the region's rapid growth and prepare for and maximize the benefit of the new transit service, the South Coast region needs intentional planning for smart growth development and environmental preservation. The scale and geographic reach of the South Coast Rail project offer an unprecedented opportunity to shape growth so that the project helps preserve environmental resources. By partnering with municipalities to jointly plan the transportation project along with local land use, the project can help cluster people and jobs near train stations, opening up new economic development opportunities, while directing growth away from natural areas.

To further these project goals, MassDOT and the Executive Office for Housing and Economic Development created the South Coast Rail Economic Development and Land Use Corridor Plan (the Corridor Plan). The implementation of the Corridor Plan supports the Commonwealth's sustainable development principles, including revitalizing gateway cities and focusing growth in places that make sense.

Section 5.5 of the FEIS/FEIR was prepared by MassDOT in response to requirements in the Secretary's Certificate on the DEIS/DEIR and other comments on the DEIS/DEIR related to the implementation of the Corridor Plan. Section 5.5 is focused on evaluating and monitoring smart growth development in the South Coast region, which is coordinated with the development of South Coast Rail service. The report provides performance metrics for the Corridor Plan and a plan for monitoring and reporting on the Corridor Plan implementation.

Executive Order 525, issued by Governor Deval Patrick in September 2010, provides for the implementation of the Corridor Plan. Executive Order 525 directs state agencies to make infrastructure and land protection investments consistent with the priority areas identified on the Corridor Map of the Corridor Plan. The priority areas include 33 priority development areas (PDAs), 72 priority protection areas (PPA), and two combined PDA/PPAs. Massachusetts' state agencies are now using the Corridor Plan to guide investments in infrastructure and land protection, and to target technical assistance where it is most needed. The Commonwealth is currently concluding a 5-year update of the Corridor Plan, starting with a review of the original 2008 designations and integrating changes that arose during the intervening years, which resulted in recommended changes to some of the PDAs and PPAs. The update process will conclude with a state review later in 2013. A description of the process and the updated mapping can be accessed by visiting SRPEDD's website at www.srpedd.org.

In order to facilitate smart growth planning efforts by communities in the South Coast Region, a total of $939 million in investment was targeted to South Coast cities and towns in FY 2009-2011, and nearly three-quarters of that funding was directed to the PPAs or PDAs outlined in the Corridor Plan. The Executive Order mandates policy commitments made in the Corridor Plan for "Strategic Investments" by committing the Commonwealth to use its discretionary grant funds and its investments in state buildings and infrastructure to support the recommendations of the Corridor Plan.

In order to provide technical assistance to all communities throughout the Commonwealth, the Executive Office of EEA has developed a Smart Growth/Smart Energy Toolkit that provides information and technical assistance to a variety of users, including planners, developers, and designers, who are interested in implementing smart growth principles for individual projects or communities. The Smart Growth/Smart Energy Toolkit provides examples of Massachusetts communities utilizing the individual tools identified in the toolkit to implement smart growth principles, but no examples are provided of comprehensive smart growth planning linked to specific metrics to monitor the implementation of smart growth principles.

According to the Secretary's Certificate on the DEIR, "the evaluation plan should include a monitoring component to assess the accuracy of impacts projections and allow for mid-course corrections and adaptive strategies as needed." These metrics assess impacts such as growth projections, as well as forestland, farmland and wetland impacts that were projected in the FEIR/FEIS for the business-as-usual and smart-growth scenarios with the actual impacts to these resources. The impacts associated with these scenarios would vary depending on the level of implementation of the Corridor Plan. The Evaluation Plan compares predicted impacts with actual impacts to assess the success of the Corridor

Plan. MassDOT would collect data so that it may notify other state agencies and municipalities that have the ability to make "corrections and adaptive strategies" as required by the Secretary's Certificate.

Currently Executive Order 525 mandates policy commitments made in the Corridor Plan for "Strategic Investments" by committing the Commonwealth to use its discretionary grant funds and its investments to target technical assistance and infrastructure investments to priority areas, to the maximum extent feasible. The Executive Order requires annual reporting by directing the Department of Administration and Finance (A&F) to develop a retrospective analysis to measure the consistency of state investment commitments with the Corridor Plan in addition to web-based tracking tool. More than 245 state investment commitments, made between Fiscal year 2009 and Fiscal year 2011 in the South Coast Region, were reviewed as part of A&F's retrospective analysis.

As noted in the Retrospective Report, agencies have undertaken the following implementation actions to ensure compliance:

- Developing a strategic plan, by agency, for implementing the Executive Order, which will include considerations and issues raised in this report;
- Collecting data to report the implementation of the Executive Order by agency, which will be summarized in an annual report;
- Seeking approval from other agencies for investments that are inconsistent with the Corridor Plan (for example, the Executive Office of EEA would need to justify an exception to the Executive Order 525 for land conservation in a PDA); and
- Targeting technical assistance and infrastructure investments to priority areas, to the maximum extent feasible.

In addition to the Retrospective Report and web based tracking tool, the Executive Order also directed A&F to collect and report state investment commitments each year in the region. These commitments will be used to measure consistency with the Corridor Plan. The first annual analysis will be released in Fall 2013.

As part of the monitoring and reporting program, MassDOT would be responsible for the reporting of results of performance metrics evaluation. MassDOT would draft a report, which would be published on MassDOT's website. The first report would be published approximately four years after the commencement of South Coast Rail service. Subsequent reports would be available every three years after this first report, for a maximum of 20 years. The first report would include data collected for the baseline year (the first year of construction of South Coast Rail) and for the subsequent three years. Each subsequent report would include the historical data, as well as data from the additional reporting period.

The Secretary's Certificate specifically requested that MassDOT form a Working Group devoted to the implementation of the Corridor Plan. To meet this requirement, MassDOT convened the Interagency Coordination Group (ICG) Smart Growth Working Group, a subset of the ICG and included representatives from the U.S. Environmental Protection Agency (USEPA), the Executive Office of Housing and Economic Development (EOHED), the Executive Office of EEA, MassDEP, and the RPAs. The purpose of the ICG Smart Growth Working Group was to develop evaluation indicators and metrics. MassDOT worked closely with EOHED and SRPEDD staff to develop the range of metrics. MassDOT convened a

meeting on April 16, 2012, with the Working Group, to present proposed performance metrics. Following the April meeting, MassDOT refined the performance metrics based on the feedback at that meeting and subsequent coordination with the regional planning agencies and EOHED. The Smart Growth Working Group met again on June 27, 2012. At this meeting, MassDOT proposed a monitoring and evaluation plan to assess the accuracy of impact projections and allow for mid-course corrections and adaptive strategies as needed and performance metrics to evaluate the effectiveness of smart growth plans and environmental protection strategies. The monitoring and evaluation plan is summarized in Section 5.5 of this FEIS/FEIR.

P7 REQUIREMENTS OF THE SECRETARY'S CERTIFICATE

This section of the Preface documents how the FEIS/FEIR responds to the requirements under MEPA, as set forth in the Secretary's Certificate on the DEIS/DEIR. The Certificate required that MassDOT prepare a Final EIR in accordance with the general guidance in the MEPA regulations (Section 11.07), including maps, plans and other graphics, environmental impacts, a list of permits required, and a list of all applicable MEPA review thresholds. Table P-1 identifies the major topics of the Certificate, and where specific information required by the Certificate can be found in this FEIS/FEIR. Volume III: Response to Comments provides a detailed response to each of the requirements of the Secretary's Certificate and to public comments.

Table P-1 Summary of the Requirements of the Secretary's Certificate on the DEIS/DEIR

Topic	Requirement	Addressed in FEIS/FEIR Chapter(s) and Section(s)
Wetlands and Biodiversity	Address the requirements of the Wetland Variance	4.16
	Evaluate wetland impacts	4.16
	Update the vernal pool impact assessment	4.14, 4.16
	Evaluate mitigation measures for impacts to wetlands and wildlife habitat	4.14
	Provide detailed information on stream crossings and culverts to enhance wildlife and fish passage	4.14, 4.16
	Evaluate the feasibility of the proposed trestle	4.16
Wetland Mitigation	Identify lands targeted for acquisition for mitigation to protect wildlife habitat and biodiversity	7.0
	Include a detailed wetland mitigation plan	7.0
Endangered Species	Consult with NHESP concerning additional impact analysis	4.15
	Include a detailed quantification of impacts to state-listed species, and a detailed plan for minimization and mitigation of impacts	4.15
	Include a comprehensive description of how MassDOT proposes to meet MESA regulatory requirements	4.15
Fisheries	Evaluate the potential impacts to fishery resources, and explain how the project will be designed to avoid adverse impacts to stocked trout waters.	4.14
Biodiversity	Include additional information on impacts to migratory birds, and measures to protect breeding birds.	4.14
Open Space	Include a detailed plan to avoid and minimize impacts to open space	4.10
	Include an update on consultations with the National Park Service concerning the Taunton River	4.10, 8.0

Topic	Requirement	Addressed in FEIS/FEIR Chapter(s) and Section(s)
	Describe proposed measures to avoid or minimize construction and operational noise impacts to wildlife in the Acushnet Cedar Swamp	4.10
	Demonstrate compliance with the EEA Article 97 Land Disposition Policy	4.10, 8.0
Layover Facilities	Expand on the analysis of layover facilities with detailed plans and a comparative analysis of environmental impacts.	3.0
	Identify permit requirements and compliance with applicable regulatory requirements, including Chapter 91 and requirements for work within a Designated Port Area.	3.0, 4.18
	Include clear commitments to specific measures to minimize or mitigate impacts, particularly visual impacts to the Taunton River.	3.0, 4.5, 7.0
Stations	Include additional information on feeder bus or shuttle bus service to the stations.	3.0
	Include additional information on station design, including analysis of decked parking, environmentally sensitive site design, and updated information on potential TOD.	3.0
	Update the ridership estimates as applicable.	3.0
	Provide additional information on pedestrian and bicycle access	3.0
Stormwater	Describe how the project will comply with the Massachusetts Stormwater Standards.	3.0, 4.17, 8.0
	Include a detailed evaluation of environmentally sensitive site design and low impact development practices.	3.0, 4.17
	Include information on stormwater peak runoff rates	3.0, 4.17
	Include details on proposed stormwater management along the proposed rail tracks.	3.0, 7.0
	Include a detailed description of the proposed stormwater management system for all components of the project.	3.0, 4.17
Coastal Zone	Describe project consistency with DPA uses and compatibility issues with regard to coastal zone protection.	4.18, 8.0
Chapter 91	Consult with MassDEP and provide more detailed plans concerning the Chapter 91 status of stations and layover facilities.	4.18
	Include analysis and mitigation as applicable to support a Public Benefits Determination.	4.18
	Identify and describe all components of the project requiring Chapter 91 licensing, and how the project will meet licensing standards.	4.18, 8.0
Air Quality	Include an evaluation of alternative fuels for the feeder bus services and describe specific commitments that MassDOT will make to contribute toward VMT and GHG emissions reductions through the feeder bus system.	4.9
	Reiterate the construction-related mitigation measures as part of a comprehensive mitigation plant.	4.9, 7.0
	Identify design and operational features to promote the reduction of GHG emissions associated with TOD and induced growth.	4.9
Noise and Vibration	Include a detailed evaluation of those locations that will experience noise impacts, and commitments to specific mitigation measures.	4.6, 7.0

Topic	Requirement	Addressed in FEIS/FEIR Chapter(s) and Section(s)
	Include a detailed mitigation plan.	
	Compare estimated vibration levels to existing conditions and describe the actual change in vibration that would be experienced. Include a mitigation plan with clear and specific commitments to address vibration impacts.	4.7, 7.0
Environmental Justice	Include a list of specific mitigation commitments to address noise and vibration impacts to EJ neighborhoods.	4.4, 7.0
	Include an update on the investigation of potential adverse effects on any traditional cultural properties of significance to Native American tribes.	4.8
	Include a discussion of how EJ populations may be affected by increased property values and how this will be addressed by MassDOT.	4.4
Cultural Resources	Include an update on historical and archeological studies, and an update on consultations with the MHC and local historical societies.	4.8
	Expand on the analysis in the DEIS/R with a detailed mitigation plan for impacts to significant historical and archaeological resources.	4.8, 7.0
	Include an update on consultations with Native American Tribes and describe potential impacts to properties of significance to the tribes.	4.8
Traffic and Safety	Evaluate the potential for increases in accident rates at grade crossings and identify specific measures to protect public safety.	4.1
	Revise the traffic mitigation plans as necessary based on further analysis.	7.0
Corridor Plan	Include an update on the status of implementation of the Corridor Plan and explain how it will be implemented.	5.5
	Develop a long-term Smart Growth Evaluation and Environmental Stewardship Plan, including metrics to evaluate how effective the project is in furthering social equity and environmental justice.	5.5
Section 61 Findings	Include revised Section 61 Findings.	7.0
Mitigation	Include a separate chapter on mitigation measures, which should include a table of all mitigation commitments as well as the revised Section 61 Findings.	7.0
Response to Comments	Include responses to comments to the extent that they are within MEPA jurisdiction.	Volume III
Circulation	The FEIR should be circulated in compliance with Section 11.16 of the MEPA regulations, and copies should be sent to the list of “comments received” below. A copy of the FEIR should be made available for public review at the Public Libraries in the South Coast region municipalities.	8.0, 9.0

1 EXECUTIVE SUMMARY

1.1 INTRODUCTION

On May 8, 2008, the Massachusetts Executive Office of Transportation and Public Works (EOT) (currently known as the Massachusetts Department of Transportation, or MassDOT) submitted an application to the U.S. Army Corps of Engineers (USACE or the Corps) under Section 404 of the Clean Water Act and potentially Section 10 of the Rivers and Harbors Act of 1899 for a Department of the Army (DA) permit to discharge fill material into waters of the United States (U.S.), including adjacent wetlands, incidental to the construction of new public passenger rail (or other public transportation) facilities connecting the terminal stations of Fall River and New Bedford with South Station in Boston, Massachusetts (the project). MassDOT (the project sponsor and state lead agency) and the U.S. Army Corps of Engineers (the federal lead agency) have evaluated several alignment and mode alternatives to implement this transit service over a distance of approximately 50 to 60 miles.

Environmental review under the National Environmental Policy Act (NEPA) and Massachusetts Environmental Policy Act (MEPA) is being conducted jointly. The Notice of Availability for the Draft Environmental Impact Statement (DEIS)/Draft Environmental Impact Report (DEIR) for the South Coast Rail Project was published in the Federal Register on March 25, 2011.[1] USACE also issued a Public Notice on March 23, 2011, in conjunction the public notice on the DEIR published in the MEPA Environmental Monitor. Approximately 270 written comment documents were submitted during the public review period of the DEIS/DEIR, with additional comments provided public hearings in New Bedford and Mansfield. The Massachusetts Secretary of Energy and Environmental Affairs approved the DEIR on June 30, 2011 and outlined information required in the Final Environmental Impact Report (FEIR).

This Final Environmental Statement (FEIS)/FEIR addresses comments on the DEIS/DEIR and provides updated environmental impact analyses to account for changes in the design of the alternatives since the DEIS/DEIR. The FEIS/FEIR also documents compliance of the Applicant's preferred alternative with the U.S. Environmental Protection Agency Guidelines for Specification of Disposal Sites for Dredged or Fill Material promulgated pursuant to Section 404(b)(1) of the Clean Water Act (Section 404(b)(1) Guidelines), at Title 40 of the Code of Federal Regulations Part 230.10 *et seq*.

1.2 PROJECT PURPOSE AND NEED

1.2.1 Purpose of the Project

MassDOT's stated purpose is "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts, and to enhance regional mobility, while supporting smart growth planning and development strategies in the affected communities."

As part of its review of the Department of the Army (DA) permit application, the USACE is required to evaluate the proposal with regard to the U.S. Environmental Protection Agency (USEPA) *Guidelines for Specification of Disposal Sites for Dredged or Fill Material* (USEPA Guidelines) at Title 40 of the Code of Federal Regulations, part 230. The basic project purpose is examined by the Corps to determine whether

[1] https://www.federalregister.gov/articles/2011/03/25/2011-7070/notice-of-availability-of-the-draft-environmental-impact-statement-for-the-proposed-south-coast-rail

the project is water-dependent. A project is water dependent if it requires access or proximity to, or siting within, a special aquatic site[2] in order to fulfill its basic purpose. The Corps has determined that the basic project purpose for the MassDOT proposal is: "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts." Since ground-based public transportation does not fundamentally require siting within a special aquatic site to meet this basic project purpose, the USEPA Guidelines stipulate that practicable alternatives are (1) presumed to exist and (2) presumed to be less environmentally damaging than the proposed action, unless clearly demonstrated otherwise.

The overall project purpose is used by the USACE to evaluate whether there are less environmentally damaging practicable alternatives available. The 404(b)(1) Guidelines state that an alternative is practicable if it is available and capable of being done after taking into consideration cost, existing technology, and logistics in light of *overall* project purposes [(40 Code of Federal Regulations (CFR) 230.10(a)(2)]. This evaluation applies to all waters of the United States, not just special aquatic sites.

Determination of the overall project purpose is the USACE's responsibility; however, MassDOT's needs and the type of project being proposed are considered by the USACE in reaching this determination. The overall project purpose is defined by the USACE as: "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, MA, and to enhance regional mobility." This definition is specific enough to define MassDOT's needs, but not so restrictive as to constrain the range of alternatives that must be considered under the USEPA Guidelines.

For purposes of the current NEPA analysis, USACE considers and expresses the proposed project's underlying purpose and need from a public interest perspective when appropriate, but generally focuses on MassDOT's purpose and need statement. The Council on Environmental Quality (CEQ) regulations at 40 CFR 1502.13, stipulate that the EIS purpose and need statement "shall briefly specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." The USACE exercises independent judgment in defining the purpose and need for the project from both MassDOT's and the public's perspectives. The purpose and need as independently determined by the USACE is: to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, MA, and to enhance regional mobility.

1.2.2 Need for the Project

The current transportation system connecting Southeastern Massachusetts with Boston and internally is primarily a highway system and characterized by a lack of transportation mode choice, especially public transit. The highway system is composed of major, limited access state routes, regional highways, and local roadways (Figure 1.2-1). As the population in the South Coast region and employment in the Boston area have grown, the demands on the roadway system linking Southeastern Massachusetts to Boston and the rest of the region have increased, as reflected by increased traffic volumes, resulting in traffic congestion and adverse effects on air quality, climate change and transportation safety. Projected regional growth and the trend of commuters to locate to areas further away from the Boston metropolitan core will exacerbate the existing problems and affect an increasing number of people.

Although important investments in regional transportation facilities and services are planned and being implemented, they are localized and would not fundamentally address the lack of regional mobility and

[2] 40 CFR Part 230 Section 404(b)(1) Guidelines for Specification of Disposal Sites for Dredged or Fill Material. Subpart E--Potential Impacts on Special Aquatic Sites.

service quality. Expansion of the existing South Coast transit services (bus, taxis, park-and-ride and vanpool) is limited by the roadway congestion.

In consideration of the above, MassDOT therefore proposes enhancement of public transit connections (collectively known as the South Coast Rail Project) to improve transportation between New Bedford/Fall River and Boston and between South Coast cities.

The South Coast Rail project is proposed by MassDOT as part of a comprehensive effort to achieve a series of broad transportation and development goals, as well as specific objectives for improving the quality of transportation services and the equity of the distribution of services within the state. These goals and objectives have been developed by MassDOT over several decades as part of both broad-based policies and specific regional documents, including the *GreenDOT Policy Directive* (2010), *South Coast Rail Plan for Action* (2007), *MBTA Program for Mass Transportation* (2003, 2010 Draft Update[3]), *Toward a New Growth Policy for Massachusetts* (1977) and *Boston Transportation Planning Review* (1970-1973). In addition to statewide plans, regional transportation goals provide a basis for evaluating options for improvement of transportation services and facilities in the South Coast region. These regional goals are included in the 2007 Regional Transportation Plans for New Bedford/Fall River/Taunton Region (adopted by the Southeastern Regional Planning & Economic Development District - SRPEDD); the Brockton Region (adopted by the Old Colony Planning Council - OCPC) and the Boston Region (adopted by the by Metropolitan Area Council - MAPC). The long-term transportation plans of the region support the development of transportation improvements that enhance accessibility, increase mobility, encourage alternatives to automobiles, and provide a more equitable distribution of transit services.

A key component of MassDOT's South Coast Rail proposal is Smart Growth, as it integrates two needs identified by MassDOT for the South Coast region that are related to transportation: *economic development* and *environmental preservation*. Southeastern Massachusetts has been the fastest growing region in the Commonwealth for many years both in terms of population and housing units and this growth has been characterized by development sprawl in exurban areas resulting in the loss of farms, fields and forests and damages to the character of the historic villages and cities within the region. At the same time, the historic cities of Fall River and New Bedford have seen a decline in population and economic vitality and their economic growth has been constrained by poor transportation access to the Boston employment market**.**

MassDOT's intent is for the South Coast Rail project to provide opportunity to generate new economic development, including that resulting from improved access from New Bedford and Fall River to labor markets in Boston and reverse commute access from areas such as Taunton to New Bedford and Fall River, while shaping this growth so that the project helps preserve environmental resources. The South Coast Rail project envisions clustering people and jobs near transit facilities in conjunction with local land use planning, thereby reducing the potential for sprawl and loss of open space. MassDOT is implementing the South Coast Rail smart growth initiatives in partnership with municipalities.

1.3 REGULATORY CONTEXT OF THE ENVIRONMENTAL IMPACT STATEMENT/ENVIRONMENTAL IMPACT REPORT

This document has been prepared to comply with the requirements of NEPA, the CEQ regulations for implementing NEPA, (Title 40 CFR Parts 1500-1508), and the USACE Regulatory Program NEPA implementing regulations at Appendix B to 33 CFR Part 325. On May 7, 2008, the USACE determined that an EIS is required for this proposed project because of the project's potential to significantly affect the quality of the human and natural environment. The purpose of this EIS is to assess the environmental impacts associated with the construction and operation of transit enhancements between Fall River/New Bedford and Boston proposed by MassDOT.

Pursuant to its responsibilities under Section 404, the USACE, therefore, has a responsibility to review permit requests seeking authorization to discharge dredged or fill material into all waters of the United States. The USACE review considers MassDOT's purpose and need from a public interest perspective, which involves more than an evaluation of impacts to the aquatic environment. Once the project has been determined to comply with the USEPA Guidelines, the project must also be evaluated to ensure that it is not contrary to the public interest. The district must evaluate the project in light of specific factors listed in 33 CFR 320.4(a) (1), other relevant public interest factors, and the interests of MassDOT to determine the overall balance of the project with respect to the public interest.

The USACE is neither a proponent nor opponent of any proposal. The decision to issue or deny a permit is based, in part on the weighing and balancing of the public interest factors. In order to issue a permit, the District Engineer must determine that it would not be contrary to the public interest (33 CFR 320.4(a)). Further, the USEPA Guidelines prohibit the issuance of a permit if the discharge is not the least environmentally damaging practicable alternative, or would cause or contribute to significant degradation of waters of the United States (40 CFR 230.10(a)(4)).

The proposed project is subject to review by the Commonwealth of Massachusetts under the MEPA because it is being undertaken by a state agency and because it meets or exceeds the review thresholds set forth in the MEPA regulations, including thresholds for a mandatory Environmental Impact Report (EIR). MEPA imposes a requirement on project proponents to understand and fully disclose the potential impacts of a project, both positive and negative; to study feasible alternatives to a project; and to avoid, reduce, or mitigate environmental impacts to the maximum extent feasible. Because the proposed project is being undertaken by a state agency MEPA jurisdiction is broad and extends to all aspects of the project that are likely, directly or indirectly, to cause damage to the environment as defined in the MEPA regulations.

In order to streamline the environmental review process and to facilitate public involvement, MEPA and the USACE are coordinating review of a joint EIS/EIR with the intent to provide the information and analysis required for both federal and state review.

Additional state approvals, reviews and permits required for the project include a Water Quality Certification pursuant to Section 401 of the Clean Water Act, and a Chapter 91 License[4] and a Variance under the Wetlands Protection Act (WPA) from the Massachusetts Department of Environmental Protection (MassDEP). Other permits or approvals required for the project include a Conservation and Management Permit from the Natural Heritage and Endangered Species Program (NHESP). The project

[4] Massachusetts General Law (MGL) Chapter 91. The Massachusetts Public Waterfront Act. Regulatory program pertaining to tidelands and other waterways.

is subject to review by the Massachusetts Historical Commission and the Office of Coastal Zone Management. The project is also subject to the MEPA Greenhouse Gas Emissions Policy and Protocol.

1.4 ALTERNATIVES

1.4.1 Alternatives Development

This section explains the process that led to the alternatives that are evaluated in this FEIS/FEIR. The alternatives analysis process included review of 65 potential alternatives during the scoping process, detailed transportation and environmental impact analyses of seven build alternatives in the DEIS/DEIR, and post-DEIS/DEIR technical studies and interagency coordination. Throughout the alternatives analysis process public, agency and stakeholder input was taken into consideration in the development and evaluation of alternatives, through the federal process, the state environmental review process and public involvement efforts. The Interagency Coordinating Group (ICG)[5] provided an opportunity for input into the technical analyses for the DEIS/DEIR and was also consulted during the FEIS/FEIR process.

An overview of key steps in the alternatives analysis process is provided below, with further detailed information being provided in Chapter 3, *Alternatives*.

1.4.1.1 Initial (PRE-DEIS/DEIR) Alternatives Analysis Overview

An initial range of 65 potential alternatives was identified by reviewing previous studies and soliciting input from the MBTA, the Interagency Coordinating Group, the Commuter Rail Task Force,[6] and interested stakeholders through an extensive civic engagement process conducted by MassDOT. The alternatives are described in detail in the Analysis of South Coast Rail Alternatives: Phase 1 Report, Appendix 3.1-A to this FEIS/FEIR.

These alternatives also included several different components along five main corridors:

- The Attleboro route (using the active freight rail lines from New Bedford and Fall River to Attleboro, then using the Northeast Corridor from Attleboro to South Station) with a new track bypass or connecting at the existing Attleboro Station.

- The Mansfield route (using the active freight rail lines from New Bedford and Fall River to Taunton, then using the abandoned rail line north to Mansfield Station, then using the active commuter rail line to South Station).

[5] The Interagency Coordinating Group (ICG) was convened by MassDOT and includes representatives of the United States Army Corps of Engineers; United States Environmental Protection Agency; United States Fish and Wildlife Service; Federal Highway Administration; Federal Transit Administration; National Marine Fisheries Service; Narragansett Indian Tribe; Wampanoag Tribe of Gay Head (Aquinnah); Massachusetts Executive Office of Energy and Environmental Affairs; Massachusetts Environmental Policy Act Office; Massachusetts Bay Transportation Authority; Massachusetts Department of Environmental Protection; Massachusetts Office of Coastal Zone Management; Massachusetts Department of Conservation and Recreation, Areas of Critical Environmental Concern Program; Massachusetts Department of Fish and Game, Natural Heritage and Endangered Species Program; Massachusetts Historical Commission and the Southeastern Regional Planning and Economic Development District.

[6] The Commuter Rail Task Force was formed in 2004 and provides a forum for state officials and local representatives to review and discuss all aspects of the Project and to work toward consensus on strategies and actions to plan ahead for new growth in the region. The Task Force provides advice and assistance to MassDOT and the MBTA in the design of the South Coast Rail Project and in the implementation of the South Coast Rail Economic Development and Land Use Corridor Plan. Its membership includes representatives from the MBTA, regional transit authorities, cities and towns, environmental groups, and business and economic development organizations.

- The Stoughton route (using the active freight rail lines from New Bedford and Fall River to Taunton, then using the inactive rail bed north to Stoughton, then using the active commuter rail tracks to South Station).

- The Middleborough route (using the active freight rail lines from New Bedford and Fall River to the existing Middleborough/Lakeville Station, then using the Old Colony Middleborough Line to South Station).

- The Highway route (using Routes 140, 79, 24, 128, and I-93 to the existing Route 128 commuter rail station, the existing Quincy Adams Red Line station, or South Station).

A step-by-step screening process was used to narrow the range of alternatives. The screening analyses considered the ability of alternatives meet the purpose and need for the project, whether they were practicable to construct and operate, and environmental impacts.

At the conclusion of the ENF review and public scoping process, the Secretary of EOEEA on April 3, 2009 issued a Certificate that specified the analyses, studies, and information to be included in the DEIR and the alternatives to be evaluated:

- No-Build Alternative (Enhanced Bus)

- Attleboro Electric Alternative (Previously referred to as Alternative 1, Option 1B)

- Attleboro Diesel Alternative (Previously referred to as Alternative 1, Option 1A)

- Stoughton Electric Alternative (Previously referred to as Alternative 4, Option 4B)

- Stoughton Diesel Alternative (Previously referred to as Alternative 4, Option 4A)

- Whittenton Electric Alternative (Previously referred to as Alternative 4, Option 4D)

- Whittenton Diesel Alternative (Previously referred to as Alternative 4, Option 4C)

- Rapid Bus Alternative (Previously referred to as Alternative 5 - Rapid Bus)

During the preparation of the DEIS/DEIR a new "Hybrid Alternative" that combined the Middleborough Simple Rail Alternative with the Rapid Bus Alternative was evaluated at the request of EPA. The evaluation indicated that complementing the low ridership of the Middleborough Simple Alternative with the ridership of the Rapid Bus Alternative would result in a combined ridership for the Hybrid Alternative less than that of the Rapid Bus Alternative by itself and just slightly more than the Middleboro Simple Alternative (which was already considered underperforming in terms of ridership). The combination alternative would require much of the infrastructure improvements needed for each individual alternative, resulting in a higher cost of the hybrid alternative than either the Rapid Bus Alternative or the Middleboro Simple Alternative. This would render the cost of the combination alternative impractical (i.e., fewer riders but higher cost of either Rapid Bus or Middleboro Simple alone). This alternative was therefore not advanced for further analysis in the DEIS/DEIR.

Along with the identification of alternative alignments, potential station sites were identified. Potential station locations to serve each of the five public transportation alternatives were identified for each

alternative and evaluated with regard to their ability to meet the Project Purpose, practicability and environmental considerations.

Potential station locations for the South Coast Rail alternatives were initially identified by the Southeastern Regional Planning & Economic Development District (SRPEDD),[7] and screened in an iterative process by the multi-disciplinary project team. SRPEDD staff with input from the public identified a total of 73 rail and bus station locations, some of which overlapped, totaling 55 rail stations and 30 bus stations. The locations identified include stations that are located on all potential rail segments, including the Fall River Secondary, New Bedford Main Line, the rail bed that extends south of the Stoughton Station, Whittenton Branch variation on the Stoughton alternative, Attleboro Secondary, and Middleborough Secondary.

1.4.1.2 Alternatives Analyzed in the DEIS/DEIR

The following alternatives were analyzed in detail in the DEIS/DEIR. The alternatives analyzed in the DEIS/DEIR were distinguished between No-Build and Build. Among the Build Alternatives there was a rail mode and a bus mode. Within the rail mode, there were three different corridors (Attleboro, Stoughton and Whittenton) and two different propulsion alternatives: electrically powered and diesel powered, as follows:

- No-Build (Enhanced Bus) Alternative
- Commuter Rail Alternatives
- Attleboro Alternative
- Attleboro Electric
- Attleboro Diesel
- Stoughton Alternative
- Stoughton Electric
- Stoughton Diesel
- Whittenton Alternative
- Whittenton Electric
- Whittenton Diesel
- Rapid Bus Alternative

The corridor for the Whittenton Alternative was a variant of the Stoughton Alternative. The Whittenton Alternative corridor avoids the Pine Swamp by using the out-of-service Whittenton Branch right-of-way and a portion of the active Attleboro Secondary rail line. It is identical to the Stoughton Alternative corridor in all other respects.

[7] SRPEDD is a regional planning agency serving 27 cities and towns in Southeastern Massachusetts.

During the DEIS/DEIR analysis, conceptual operating plans, capital improvement requirements, capital costs, and operating and maintenance costs were developed for each alternative. DEIS/DEIR alternatives were modeled by the Central Transportation Planning Staff (CTPS) using their regional transportation model, providing quantitative results on the performance of each alternative in terms of ridership, highway/vehicular travel, air quality, and environmental justice. Detailed analyses of environmental impacts (to natural resources, air quality, noise and vibration, historic resources, social and economic impacts among others) were conducted. Smart growth strategies were as identified in the South Coast Rail Corridor Plan were evaluated for all Build Alternatives analyzed in the DEIS/DEIR.

1.4.1.3 Alternatives Eliminated Following the DEIS/DEIR

This section briefly describes the alternatives eliminated following the DEIS/DEIR and the rationale for not advancing these alternatives to this FEIS/FEIR.

Attleboro Alternatives

The Attleboro Alternatives would provide commuter rail service to South Station using the Northeast Corridor, proposed Attleboro Bypass, Attleboro Secondary, New Bedford Main Line, and Fall River Secondary. Both electric (Attleboro Electric) and diesel (Attleboro Diesel) commuter rail options were evaluated for this alternative. The New Bedford route would be 60.4 miles long and the Fall River route would be 57.9 miles long.

Based on the RAILSIM capacity simulations, the Attleboro Alternatives would operate with very poor on-time performance (especially in the evening peak period) (See Appendix 3.1-D). The analysis indicated that the Attleboro Alternatives would be operationally infeasible as they would not meet the MBTA on-time standard in the morning peak and would experience even worse on time performance during the evening peak commute. The Attleboro Alternatives would also contribute to a cascading negative impact on the on-time performance of the entire southerly commuter rail system, including Worcester, Franklin, Needham, and Providence commuter rail lines.

In order to address the operational infeasibility of the Attleboro Alternative, capacity on the Northeast Corridor (NEC) would have to be increased through construction of a fourth track along the NEC between Forest Hills Station and Back Bay Station. An analysis was conducted in the DEIS/DEIR of the construction costs and schedule implications as well as key property and other impacts associated with the construction of a fourth track. The analysis in the DEIS/DEIR (Section 1.4.6.2) indicated that the potential impacts, construction costs and construction schedule and other aspects of the fourth track along the NEC would render implementation of this infrastructure requirement not practicable considering costs, existing technology and logistics in light of overall project purposes. In a previous study, the Federal Railroad Administration (FRA; a cooperating federal agency) also explored the option to expand capacity of the NEC north of Canton Junction Station. However, due to substantial constraints, it was proposed that such capacity expansion end at Forest Hills in Jamaica Plain. In reviewing the RAILSIM capacity simulations conducted for the Attleboro Alternative, the FRA indicated to the Corps during the preparation of the DEIS/DEIR that it considered the Attleboro Alternatives infeasible and appropriate to eliminate from further environmental review/ consideration.[8] Accordingly, the Corps has determined that the Attleboro alternatives are not practicable, after taking into consideration cost, existing technology and logistics in light of overall project purposes (40 CFR 230.10(a)(2)), and therefore, the alternative was eliminated from further consideration in the FEIS/FEIR

[8] Email correspondence from FRA to Army Corps. March 3, 2010.

Rapid Bus Alternative

As proposed at the time of the DEIS/DEIR, the Rapid Bus Alternative would provide commuter bus service to South Station via I-93, Route 140 and Route 24. North of I-495, buses would use a combination of new zipper bus lanes, new reversible bus lanes, two-way bus lanes, existing zipper high occupancy vehicle (HOV) lanes, and existing HOV lanes, along with a short section in mixed traffic. South of the I-495 interchange in Raynham, buses would travel in the general purpose lanes with mixed traffic. The New Bedford route would be 56.4 miles long and the Fall River route would be 51.5 miles long.

This alternative requires improvements to highway infrastructure along Route 24 (construct third lane from Route 140 to I-495, a distance of 5.8 miles; widen Route 24 to accommodate movable barriers; construct zipper bus lane from I-495 to Harrison Boulevard, a distance of 15.4 miles); and Route 128/I-93 (construct reversible bus lane from Harrison Boulevard on Route 24 to Logan Express Lot, a distance of 4.2 miles; and construct two-lane bus roadway from Logan Express Lot to existing HOV zipper lane on the Southeast Expressway, a distance of 1.6 miles). Infrastructure improvements also include constructing, reconstructing, or widening 20 bridges and reconstructing 11 highway interchanges.

In response to the comments received on the DEIS/DEIR, the Rapid Bus Alternative was re-evaluated and modified to attempt to improve ridership performance and eliminate bottlenecks. Multiple alternatives were developed and evaluated based on the criteria established in the DEIS/DEIR. The changes that were selected and became part of the Modified Rapid Bus Alternative are described in detail in Appendix 3.1-E: *Modified Rapid Bus Alternative Technical Memorandum*.

In developing the Modified Rapid Bus Alternative several major constraints and concerns were identified:

- A fully exclusive bus lane (to reduce travel time) could not be feasibly constructed all the way into Boston;
- Because the Modified Rapid Bus Alternative requires the use a section of the existing highway system that is already subject to heavy congestion and is vulnerable to significant delays, the reliability of the Modified Rapid Bus Alternative would be severely impacted, which would negatively affect ridership;
- Annual operating and maintenance costs of the Modified Rapid Bus Alternative would be more than double those of the Stoughton Electric Alternative; and
- The Modified Rapid Bus Alternative would have twice as much wetland impact (in area) as the DEIS/DEIR Stoughton Electric Alternative and approximately 30 percent less air quality benefit based on a reduction of annual carbon dioxide (CO_2) emissions from commuters switching from automobiles to the public transportation options under consideration.
- In sum, the Modified Rapid Bus Alternative would still have substantially lower ridership, much higher cost and greater adverse environmental impact compared to the commuter rail alternatives.

The Federal Highway Administration (FHWA) provided its review of the DEIS/DEIR Rapid Bus Alternative and subsequent related information (including the Modified Rapid Bus Alternative).[9] The role of the Federal Highway Administration (FHWA) as a cooperating agency on the EIS for the South Coast Rail project is to provide special expertise and technical assistance with respect to issues concerning the transportation system. The FHWA commented that "Based on the information provided in the DEIS and related materials, it is our opinion that the analysis of the Rapid Bus Alternative accurately presents the impacts to the transportation corridor and the region. Furthermore, FHWA believes that the impacts to the roadway network, in particular those which degrade service on the Interstate System associated with the Rapid Bus Alternative and its various modifications are unacceptable, and thus the alternative is not a viable option"

In sum, the substantial analysis conducted for the Rapid Bus Alternative during the DEIS/DEIR and subsequent consideration of optimized Modified Rapid Bus Alternatives (see Appendix 3.1-E), including its multiple design variations, indicates very low ridership, fewer regional mobility benefits (interregional links), greater impact on the environment and on the transportation system than the rail alternatives and high cost of the (Modified) Rapid Bus Alternative and its variants. The Corps has thoroughly considered this data and the determination by the FHWA (in its capacity as a Cooperating Agency with technical expertise on this alternative) of this alternative as non-viable. The Corps concludes that, at best, the Modified Rapid Bus Alternative (1) meets the overall project purpose only marginally by generating approximately 1/3 fewer riders than MassDOT's preferred alternative, (2) is unreasonably costly to construct and maintain (more than double the annual operating and maintenance cost of the Stoughton Electric Alternative), and (3) is logistically infeasible to construct in a manner that would not be highly likely to eventually degrade the already stressed Interstate Highway transportation system. Accordingly, the Corps has determined that the Modified Rapid Bus alternative is not practicable, after taking into consideration cost, existing technology and logistics in light of overall project purposes (40 CFR 230.10(a)(2)), and therefore, the alternative was eliminated from further consideration in the FEIS/FEIR.

1.4.2 Description of Alternatives Evaluated in the FEIS/FEIR

This section provides a description of the alternatives evaluated in the FEIS/FEIR: the No-Build (Enhanced Bus) Alternative, the Stoughton Alternative (electric and diesel variants) and the Whittenton Alternative (electric and diesel variants).

An overview of the rail corridors within which the proposed Build Alternatives would be constructed is presented first. The organization of the description of these corridors forms the basis for the characterization of the affected environment and environmental consequences of the rail alternatives in Chapter 4. Figure 1.2-1 provides an overview of the various rail corridors discussed in this section.

A summary of Build Alternatives modes follows the overview of rail corridors.

[9] Letter from FHWA to USACE re: South Coast Rail Project. January 17, 2013.

1.4.2.1 Overview of Build Alternatives Corridors

The "Southern Triangle"

This section, common to all rail alternatives, provides an overview of two components of the transportation system south of Weir Junction, referred to as the "Southern Triangle." These components include the New Bedford Main Line and the Fall River Secondary.

New Bedford Main Line Rail Segment

The New Bedford Main Line is an active rail line running from the Attleboro Secondary at Weir Junction in Taunton to the waterfront piers in New Bedford. The line connects with the Middleborough Secondary at Cotley Junction and the Fall River Secondary at Myricks Junction. The line is in service for freight only at the present time. The line is mostly single track (but was constructed to carry two tracks), with a two-track section north of Cotley Junction. The line was acquired from CSX by MassDOT.

The line passes through some environmentally sensitive areas, including the Assonet Cedar Swamp in Berkley and Lakeville and is adjacent to the Acushnet Cedar Swamp State Reservation in New Bedford. Other constraints include dense development along the line in New Bedford.

Fall River Secondary Rail Segment

The Fall River Secondary is an active rail line running between the New Bedford Main Line at Myricks Junction in Berkley and the waterfront in Fall River. The line is in service for freight only at the present time. The line is all single-track, and was acquired by MassDOT from CSX.

The line passes through some environmentally sensitive areas, including the Assonet Cedar Swamp in Berkley. Other constraints include dense development along the line in Fall River, and large slopes above and below the line in Fall River along the Taunton River.

Northeast Corridor Rail Segment

The Northeast Corridor is an active rail line running between New York and South Station in Boston. The portion of interest for this project runs from Attleboro to Boston. The corridor experiences heavy use, including Amtrak Regional and Acela service, MBTA commuter rail service, and freight rail service. The MBTA Providence Line uses the entire length of this portion of the corridor; the Stoughton Line, Franklin Line, and Needham Lines join farther north at Canton Junction, Readville, and Forest Hills, respectively.

The corridor has at least two tracks on this section, with three tracks from Readville to Boston. There are also two station siding tracks at Attleboro Station. The corridor is electrified, meaning that both diesel and electric trains can operate, and is designed and signaled for high-speed rail operations. The corridor is owned by the MBTA. Train operations are controlled by Amtrak.

Attleboro Secondary Rail Segment

The Attleboro Secondary is an active rail line running from the Northeast Corridor in Attleboro to the Stoughton Line and New Bedford Main Line at Weir Junction in Taunton. The line is in service for freight only at the present time. The line is mostly single track, with a two-track section just east of the Northeast Corridor in Attleboro. The line is currently owned by MassDOT and operated by CSX.

The line runs through some environmentally sensitive areas, including Chartley Pond and the Three Mile River Area of Critical Environmental Concern (ACEC). It also has many grade crossings in downtown Taunton, because it runs directly through the densely developed core of the city.

Stoughton Alternatives Corridor

This section provides an overview of the Stoughton Main Line, the main component of the transportation corridor for the Stoughton alternatives under consideration. Alternatives through Stoughton would also use the Northeast Corridor north of Canton Junction.

The Stoughton Main Line is a rail line running from the Northeast Corridor at Canton Junction to the Attleboro Secondary and New Bedford Main Line at Weir Junction in Taunton. The line is active between Canton Junction and Stoughton Station serving commuter rail on the MBTA Stoughton Line and freight rail to customers in Canton and Stoughton. A short piece of the line north of Weir Junction is active, serving freight only. The remainder of the line, from Stoughton Station to Taunton, is out of service, and some tracks were removed.

The active sections of the corridor are single-track, except at the approach to Canton Junction, where there are two tracks. The corridor is owned by the MBTA, north of Britton Street in Raynham. Parts of the right-of-way north of Longmeadow Road in Taunton were sold and in various public/private ownership. The active freight rail segment north of Weir Junction is owned by MassDOT and operated by the MassCoastal Railroad.

The corridor passes through some environmentally sensitive areas, including Pine Swamp in Raynham and the Hockomock Swamp ACEC in Raynham and Easton. Hockomock Swamp is one of the most important wetlands in the state for rare species habitat and protects regional water quality.

Whittenton Alternatives Corridor

This section provides an overview of the main component of the transportation corridor for the Whittenton alternatives under consideration. Like the Stoughton alternatives, the Whittenton alternatives would use the Northeast Corridor north of Canton Junction to the Stoughton Main Line to the Whittenton Branch. The Whittenton Branch is an out-of-service rail line in Raynham and Taunton, running around the northwest edge of the core of the City of Taunton and connecting the Stoughton Line with the Attleboro Secondary.

The corridor runs through the Hockomock Swamp ACEC in Easton and Raynham, but would avoid impacts to Pine Swamp in Raynham. The Whittenton Branch is currently owned by the MBTA.

1.4.2.2 Description of Build Alternatives Modes

This section discusses the modes used by the FEIS/FEIR alternatives and the operating assumptions used to evaluate each mode.

Diesel Commuter Rail

Diesel commuter rail refers to a fixed-guideway system with steel wheels operating on steel rails, with one or two locomotives pulling a number of passenger coaches; on the MBTA system, trains are generally six to nine coaches. Coaches would be bi-level, to increase capacity. Diesel commuter rail maximum speed was assumed to be 79 mph, the maximum currently operated on the MBTA system.

While the maximum speed would be 79 mph, actual operating speeds would often be lower due to station stops, curves, and other track features.

Electric Commuter Rail

Electrified commuter rail refers to a fixed-guideway system with steel wheels operating on steel rails, with one or two locomotives pulling a number of passenger coaches. For consistency with the MBTA system, trains are assumed to be six to nine coaches. Coaches would be bi-level to increase capacity. Commuter rail locomotives are powered by an overhead electrical contact system. For electric commuter rail, the maximum speed was assumed to be 100 mph, the maximum speed that can be operated without incurring significant signal costs because of the need to signal civil restrictions. While the maximum speed would be 100 mph, actual operating speeds would often be lower due to station stops, curves, and other track features. The primary travel time advantage of electric commuter rail over diesel for this project is faster acceleration when departing stations (savings of approximately 20 seconds per station, see Section 1.4.3.2).

1.4.2.3 No-Build Alternative – Enhanced Bus

Under this alternative, no new rail or bus service would be provided to Southeastern Massachusetts; however, existing routes would be enhanced. The No-Build Alternative would improve transit service to Boston from New Bedford, Fall River, and Taunton by adding more buses with smaller capital investments than are proposed in the Build Alternatives (Stoughton Alternative and Whittenton Alternative). The No-Build Alternative is shown in Figure 1.4-1.

Also included in the No-Build Alternative are the expansion of South Station in Boston, the construction of new mid-day layover facilities in the Boston area and the reconstruction of railroad bridges in the New Bedford area. These improvements are proposed based on existing and future needs and would be implemented irrespective of the South Coast Rail alternatives.

1.4.2.4 Stoughton Electric Alternative

The Stoughton Electric Alternative would provide commuter rail service to South Station using the NEC, Stoughton Line, New Bedford Main Line, and Fall River Secondary. Figure 1.4 -2 shows the Stoughton Alternative. The New Bedford route would be 55.0 miles long and the Fall River route would be 52.7 miles long.

A summary of this alternative is provided Table 1.4-1. The Stoughton Alternative would:

- Utilize 15.5 miles of existing NEC track infrastructure between Boston and Canton Junction;
- Require improvements to track infrastructure along the Stoughton Line including:
    - Reconstructing existing tracks from Canton Junction to Stoughton, as double track, a distance of 3.8 miles; and
    - Constructing new tracks on existing right-of-way from Stoughton Station to Weir Junction in Taunton, as one to two tracks, a distance of 16.4 miles;
- Require reconstructing track on the Southern Triangle (common to both the Stoughton and Whittenton Alternatives), including:

- Reconstructing the existing New Bedford Main Line tracks from Weir Junction to New Bedford, as two to three tracks from Weir Junction to Myricks Junction, a distance of 4.9 miles; and single track with three sidings from Myricks Junction to New Bedford, a distance of 14.5 miles; and

- Reconstructing the existing Fall River Secondary tracks from Myricks Junction to Fall River, as single track with four sidings, a distance of 12.3 miles.

- Infrastructure improvements for the Stoughton Alternative also includes constructing, reconstructing, or widening 40 bridges and constructing or reconstructing 46 railroad at-grade crossings.

This alternative would have ten new commuter rail stations (North Easton, Easton Village, Raynham Park, Taunton, Taunton Depot, King's Highway, Whale's Tooth, Freetown, Fall River Depot, and Battleship Cove) and major reconstruction of two existing commuter rail stations (Canton Center and Stoughton). This alternative would include two overnight layover facilities, one in New Bedford and one in Fall River.

To support electric locomotives, a traction power system would be built and would include two main substations (one in Easton and one in New Bedford), two switching stations (one in Canton and one in Berkley), and six paralleling stations (one in Easton, one in Taunton, two in Freetown, one in New Bedford, and one in Fall River).

1.4.2.5 Stoughton Diesel Alternative

The Stoughton Diesel Alternative would be identical to the Stoughton Electric Alternative with the exception of the electrical facilities, which would not be required for the diesel alternative.

Table 1.4-1 Summary of Rail Alternatives

	Stoughton Alternative			Whittenton Alternative		
Segment	Length (miles)	Number of Tracks	Number of Sidings	Length (miles)	Number of Tracks	Number of Sidings
Canton to Stoughton Station	3.8	2		3.8	2	
Stoughton Station to Weir Junction	16.4	1-2		17.9	1-2	1
Weir Junction to Myricks Junction	4.9	2-3		4.9	2-3	
Myricks Junction to New Bedford	14.5	1	3	14.5	1	3
Myricks Junction to Fall River	12.3	1	4	12.3	1	4
Total Length (South Station to New Bedford)	55.0			56.6		
Total Length (South Station to Fall River)	52.7			54.3		

1.4.2.6 Whittenton Electric Alternative

The Whittenton Alternative would provide commuter rail service to South Station through Stoughton, connecting to the existing Stoughton Line using the Whittenton Branch and a short segment of the Attleboro Secondary through the City of Taunton. The Whittenton Alternative is shown in Figure 1.4-3. The New Bedford route would be 56.6 miles long and the Fall River route would be 54.3 miles long.

Table 1.4-1 presents a summary of the Whittenton Alternative. This alternative would:

- Utilize 15.5 miles of existing NEC track infrastructure between Boston and Canton Junction;
- Require improvements to track infrastructure along the Stoughton Line, including:
  - Reconstructing existing tracks from Canton Junction to Stoughton, as double track, a distance of 3.8 miles; and
  - Constructing new tracks on existing right-of-way from Stoughton to Raynham Junction, as one to two track sections a distance of 11.9 miles;
- Require constructing new singe track on existing Whittenton Branch right-of-way from Raynham Junction in Raynham to Whittenton Junction;
- Require reconstructing existing Attleboro Secondary tracks from Whittenton Junction to Weir Junction, as a single track with one siding, a distance of 6.0 miles);
- Require reconstructing track on the Southern Triangle (common to both rail alternatives) including:
  - Reconstructing the existing New Bedford Main Line tracks from Weir Junction to New Bedford, as two to three tracks from Weir Junction to Myricks Junction, a distance of 4.9 miles; and single track with three sidings from Myricks Junction to New Bedford, a distance of 14.5 miles; and
  - Reconstructing the existing Fall River Secondary tracks from Myricks Junction to Fall River, as single track with four sidings, a distance of 12.3 miles.

Infrastructure improvements for the Whittenton Alternative also include constructing, reconstructing, or widening 38 bridges and constructing or reconstructing 53 railroad at-grade crossings.

This alternative would have ten new commuter rail stations (North Easton, Easton Village, Raynham Park, Dana Street, Taunton Depot, King's Highway, Whale's Tooth, Freetown, Fall River Depot, and Battleship Cove) and major reconstruction of two existing commuter rail stations (Canton Center and Stoughton), as well as expansion of South Station. This alternative would include two overnight layover facilities, one in New Bedford and one in Fall River.

To support electric locomotives, a traction power system would be built and would include two main substations (one in Easton and one in New Bedford), two switching stations (one in Canton and one in Berkley), and six paralleling stations (one in Easton, one in Taunton, two in Freetown, one in New Bedford, and one in Fall River).

1.4.2.7 Whittenton Diesel Alternative

The Whittenton Diesel Alternative would be identical to the Whittenton Electric Alternative with the exception of the electrical facilities, which would not be required for the diesel alternative.

1.4.3 Operations of the Alternatives

1.4.3.1 No-Build Alternative

Commuter Rail Service

Under the No-Build Alterative, no commuter rail service is offered within the South Coast area. Although commuter rail service is offered in nearby southeastern Massachusetts communities by the MBTA, this service is difficult for most residents to access and is approaching or over capacity under existing conditions.

No-Build Commuter Bus Service

Existing commuter bus service to Boston from New Bedford, Fall River, and Taunton is currently provided by three commuter bus carriers: DATTCO provides Boston – New Bedford service; Peter Pan provides Boston – Fall River bus service; and Bloom provides Boston – Taunton service.

These bus companies offer a fare structure that is competitive to commuter rail service. The three commuter bus routes travel through the downtown core of New Bedford, Taunton, and Fall River. The routes all board passengers in the downtown before traveling to other locations to pickup/drop-off passengers at external bus stops/park-and-ride lots and intermediate flag stops. The Fall River commuter bus runs express to Boston with no intermediate stops.

In addition to the private commuter bus service to Boston, two regional transit authorities (RTAs) provide transit service in the study corridor: SRTA operates in New Bedford and Fall River sub-region, and GATRA operates in the Taunton/Attleboro area sub-region. Each RTA shares terminal facilities with commuter bus companies. These authorities share infrastructure and terminals with the commuter bus carriers and provide passengers an intermodal link from other points within the local communities to the Boston commuter bus service.

Detailed information regarding the existing operating schedule of the bus services in the project area is provided in Chapter 3, along with recommendations of operating schedule enhancements. While bus service operations would be improved, no major capital transit improvements serving the South Coast Region would occur under the No-Build Alternative.

1.4.3.2 Rail Alternatives

Commuter Rail Operations

The Stoughton and Whittenton Electric Alternatives have similar operating plans that were developed to meet the current minimum requirements of the MBTA Service Delivery Plan for commuter rail. The infrastructure proposed for each alternative has been designed to support these levels of operation.

The proposed operations would have four peak period trains to each of the terminal stations of New Bedford and Fall River. This translates to approximately 30-minute service on both the Fall River Secondary and the New Bedford Main Line, and an 18 minute headway on the trunk (shared) portion of the route north of Myricks Junction. During the off-peak periods, six additional trains would operate on a 3 hour frequency from the terminal stations and 90 minutes on the trunk portion. This provides 10 round trip trains per weekday from each terminal station.

Both commuter rail alternatives would use the same station stops south of Taunton Depot. By employing a zone-express service pattern (where trains stop at a few stations and then run express), travel times for passengers traveling from Fall River and New Bedford would decrease as compared to those presented in the DEIS/DEIR.

Table 1.4-2 summarizes the total trip time from each terminal station (New Bedford and Fall River) to South Station based on the revised station stopping pattern. These trip times are between 5 and 7 minutes faster than shown in the DEIS/DEIR due to the revised service plan. As shown in the table, the Stoughton Alternative would be 6 to 7 minutes faster than the Whittenton Alternative for service to New Bedford, and 8 minutes faster for service to Fall River.

Table 1.4-2 Average Trip Time Table (hr:min)

	Stoughton Electric Alternative		Whittenton Electric Alternative	
Operation	**New Bedford Trains**	**Fall River Trains**	**New Bedford Trains**	**Fall River Trains**
Peak Period Service	1:17	1:15	1:24	1:23
Non-Peak Period Service	1:16	1:18	1:22	1:26

1 Overall travel times for each branch of the Stoughton and Whittenton Electric Alternatives were developed using the Rail Traffic Controller model.
2 Assumptions were made based on track and signal layout.
3 Express trains may have longer travel times than local trains since they only operate during peak periods.

The average trip times in Table 1.4-2 are based on simulation of the Stoughton Electric Alternative. Diesel Alternatives would add approximately 20 seconds per station due to the additional time diesel locomotives need to accelerate from the stations. Deceleration rates would be identical to those of the Electric Alternatives. It is noted that although its operating plan skips a few stops, the peak period service has a longer travel time due to longer dwell times at each station in order to load and unload passengers during peak commuting hours. The off-peak period service would stop at every station but would have much shorter dwell times and would, therefore, have a shorter average travel time than the peak service.

Feeder Bus

The Feeder Bus plan for the South Coast Rail project is envisioned to connect the urbanized communities in the study area to the South Coast stations. A Feeder Bus network would provide an alternative to driving to stations and would support transit oriented development and other smart growth initiatives in the study area by connecting surrounding areas to the train station. The Feeder Bus network would provide frequent, convenient service connections with trains.

Three regional transit authorities currently provide local bus service within the region: Brockton Area Transit Authority (BAT), Southeastern Regional Transit Authority (SRTA) and Greater Attleboro Taunton Regional Transit Authority (GATRA). The SRTA and GATRA operators use a fleet of buses that accommodate bicycles, which would encourage multi-modal integration for the South Coast Rail project. Current bus operators would provide enhanced Feeder Bus service to the proposed stations for the selected build alternative.

Feeder Bus service would connect the South Coast Rail stations with the services shown in Table 1.4-3.

Table 1.4-3 Proposed Feeder Bus Operations

Station Name	Operator	Route #	Extension Length (miles)	Existing Headway (minutes)	Proposed Peak Frequency
Easton Village	BAT	8	3.0	40	same
Taunton Station	GATRA	7	0.4	30	same
Dana Street Station	GATRA	18	0.3	30	same
Taunton Depot	GATRA	8	0.2	60	same
Freetown Station	SRTA	2	1.0	30	same
Fall River Depot	SRTA	2	0.4	20	same
Kings Highway	SRTA	8	0	45	same
Whale's Tooth	SRTA	1	0.7	20	same
Whale’s Tooth	SRTA	2	0	20	same

Freight Operations

Although future freight demand was not modeled as part of the project, future operating windows for freight trains were included. Freight trains would be allowed to operate on certain sections of track, during specified time periods (see Chapter 3).

Freight service would be restricted to standard freight size and weight, and would not support high-and-wide or double-stack operations. Freight services is anticipated to continue on the track segments where freight is currently provided (on the Stoughton Line north of Stoughton Station, on the Attleboro Secondary, on the Stoughton Line in Taunton between Longmeadow Road and Weir Junction, and on the New Bedford Main Line and Fall River Secondary south of Weir Junction). No future freight service is currently planned on the out-of-service Whittenton Branch or Stoughton Line between Stoughton Station and Longmeadow Road.

1.4.4 Track Infrastructure of the Rail Alternatives

Subsequent to the DEIS/DEIR, MassDOT has advanced the preliminary track design for the Stoughton Alternative and the Whittenton Alternative. All track changes have been minor. The design of bridge structures has been advanced, particularly for the Hockomock Trestle between Foundry Street and the former Raynham Greyhound Park.

1.4.4.1 FEIS/FEIR Track Design

All of the rail alternatives require reconstructing existing active tracks and constructing new tracks either on out-of service or new rights-of-way. The new track infrastructure would consist of new 132RE rail, new rail ties, new stone ballast, subballast and other track material. The horizontal and vertical geometry for the new track has been designed to conform to the applicable design speed for the alternatives in accordance with the MBTA commuter rail design standards and American Railway Engineering and Maintenance-of-Way Association (AREMA) design standards. The alignments have also been designed to minimize impacts to adjacent environmental resources and private properties.

1.4.4.2 Track Infrastructure - Stoughton Alternative

The New Bedford Main Line from Weir Junction in Taunton to the Whale's Tooth Station, and the Fall River Secondary from Myricks Junction in Berkley to Battleship Cove Station, are segments of track common to both commuter rail alternatives as is the track from Raynham Junction to South Station. Only the segment from Raynham Junction to Weir Junction would differ between the alternatives. Except in certain locations, the track would be designed for a maximum authorized speed (MAS) of 100 MPH. Locations which would be designed for less than 100 MPH MAS would be at certain sidings (which would be too short to achieve 100 MPH), and south of the King's Highway Station, where it would be precluded by single track operations.

Stoughton Line

The existing single track commuter rail line would be upgraded and maintained to FRA Class 7. A new second track would be constructed from Canton Junction to the existing Stoughton Station, where existing passenger service ends. A new double track would extend south of Stoughton Station to the proposed North Easton Station. The remainder of the line south to Weir Junction would be single- track, with a 2.2-mile-long double-track section in Raynham, and a 0.6-mile-long double-track section in Taunton. Approaching Weir Junction, an additional 0.4-mile siding track would be provided for freight use only. Weir Junction would also be reconfigured to accommodate four tracks as well as 45 MPH for operations through the curve while maintaining existing rail connections. These track segments are listed in Table 1.4-4.

Table 1.4-4 Track Infrastructure—Stoughton Alternative

Track Segment	Single Track	Double Track	Triple Track	Quadruple Track	Total (miles)
Canton Junction to Stoughton Station[1]	-	3.8	–	–	3.8
Stoughton Station to Raynham Junction[1]	7.1	4.8	–	–	11.9
Raynham Junction to Weir Junction[1]	2.9	1.1	–	0.4	4.5
Weir Junction to Cotley Junction[2]	–	0.7	0.9	–	1.6
Cotley Junction to Myricks Junction[2]	–	3.3	–	–	3.3
Myricks Junction to Battleship Cove[3]	9.4	2.9	–	–	12.3
Myricks Junction to Whale's Tooth[2]	10.1	4.5	–	–	14.5
TOTAL (miles)	29.5	21.1	0.9	0.4	51.9

1 Stoughton Line
2 New Bedford Main Line
3 Fall River Secondary

A frontage road would be constructed in Stoughton connecting to Morton Street to eliminate multiple grade crossings, and a new grade-separated crossing is proposed at Route 138 in Raynham. A trestle section is proposed in Easton and Raynham to minimize environmental impacts to the Hockomock Swamp Area of Critical Environmental Concern.

New Bedford Main Line

The 19.4-mile existing track along the New Bedford Main Line would be upgraded and maintained to FRA Class 7 options. The line would be double-track from Weir Junction to Myricks Junction, with a 0.9-mile third track for freight movements near Taunton Depot Station. A short segment of the line would be double-track south of Myricks Junction, 0.8 mile. The remainder of the line would be single-

track, with the exception of 1.8-mile double-track section in Freetown and a 1.7-mile section in New Bedford. These sidings are required by the operations analysis and also allow flexibility between commuter and freight operations.

Fall River Secondary

The 12.3 miles of existing track along the Fall River Secondary would be upgraded and maintained to FRA Class 7 options. The majority of this line would be single-track with a 0.7-mile double-track segment at Myricks Junction. A 1.0-mile long section of double track would be installed adjacent to the Fall River Golf Club. Three double-track sections are also proposed in Freetown and Fall River, at 0.6, 0.3, and 0.2 miles long, respectively, to allow flexibility between commuter and freight operations.

1.4.4.3 Track Infrastructure - Whittenton Alternative

The route for the Whittenton Alternative is similar to the Stoughton Alternative except in Raynham and Taunton. The New Bedford route would be 56.6 miles long and the Fall River route would be 54.3 miles long. This alternative would extend through the out-of-service Stoughton Line, as previously described, and connect to the out-of-service Whittenton Branch at Raynham Junction. The Whittenton Branch would extend south and west to the Attleboro Secondary at Whittenton Junction. Along the Attleboro Secondary, the Whittenton Alternative would extend to Weir Junction in Taunton. South of Taunton, the alternative would continue on the New Bedford Main Line and Fall River Secondary track, identical to the Stoughton Alternative.

Track infrastructure improvements would include 3.6 miles of new single-track on the Whittenton Branch and 2.2 miles of single-track reconstruction on the Attleboro Secondary with a 0.3-mile siding reserved for the proposed Dana Street Station. Improvements on the Stoughton Line between Canton Junction and Route 138 in Raynham would be the same as the Stoughton Alternative. Table 1.4-5 summarizes the track infrastructure improvements along the Whittenton Alternative.

Table 1.4-5 Track Infrastructure—Whittenton Alternative

Track Segment	Single Track	Double Track	Triple Track	Quadruple Track	Total (miles)
Canton Junction to Stoughton Station[1]	–	3.8	–	–	3.8
Stoughton Station to Raynham Junction[1]	7.1	4.8	–	–	11.9
Raynham Junction to Whittenton Junction[2]	3.6	–	–	–	3.6
Whittenton Junction to Weir Junction[3]	2.2	0.3	–	–	2.5
Weir Junction to Cotley Junction[4]	–	0.7	0.9	–	1.6
Cotley Junction to Myricks Junction[4]	–	3.3	–	–	3.3
Myricks Junction to Battleship Cove[5]	9.4	2.9	–	–	12.3
Myricks Junction to Whale's Tooth[4]	10.1	4.5	–	–	14.5
TOTAL (miles)	32.4	20.3	0.9	0.4	53.5

1 Stoughton Line
2 Whittenton Branch
3 Attleboro Secondary
4 New Bedford Main Line
5 Fall River Secondary

1.4.5 Grade Crossings

The majority of existing public grade crossings on the active railroad rights-of-way have automatic grade crossing gates and flashers installed. All existing grade crossings to remain and all reactivated crossings would be equipped with new, state-of-the-art Automatic Highway Crossing Warning (AHCW) systems. Trains would use horns when they approach grade crossings, which is MassDOT's standard highest level of warning. Sounding a horn while approaching a grade crossing is a well-proven and effective method of providing warning of an approaching train. MassDOT is not proposing Quiet Zones for noise mitigation and is committed to designing the South Coast Rail project grade crossings to the safety standard provided by the Federal Railroad Administration (FRA).

Grade crossings would be closed or consolidated whenever feasible. Private grade crossings would be closed, gated, and locked if possible; if not, new AHCW systems would be installed. At a minimum each public grade crossing would consist of automatic gates, LED flashers, and an electronic bell. Where required, this standard arrangement may be supplemented with additional equipment such as additional gates and cantilevered flashers to optimize visibility for the roadway approaches.

A summary of the number of grade crossings by alternative is provided in Table 1.4-6.

Table 1.4-6 Summary of Public Grade Crossings by Alternative

Commuter Rail Alternative	Existing Active Grade Crossings	Existing Grade Crossings Recommended for Closure	Proposed New Grade Crossings[1]	Total Proposed Grade Crossings
Stoughton Alternative	31	3	15	43
Whittenton Alternative	40	3	13	50

1 Includes grade crossings that are existing but not active

1.4.6 Bridges and Culverts

All of the rail alternatives require reconstructing undergrade bridges (railroad over road or river) and overhead bridges (highway over railroad) along the active and restored rights-of-way.

Table 1.4-7 provides a general summary of required bridge improvements for the two alternatives, to enable comparison. The summary includes existing bridges to be reconstructed and new bridges required to restore/provide grade separation or traverse sensitive areas.

Table 1.4-7 Summary of Bridge Improvements by Alternative

Commuter Rail Alternative	Reconstruct Undergrade (Railroad) Bridges	Reconstruct Overhead (Highway) Bridges	New Bridges for Grade Separation or Environmental
Stoughton Alternative	31	3	6
Whittenton Alternative	29	4	5

1.4.7 Signals and Communications

The Signals and Communications design remains the same as described in the DEIS/DEIR. The following sections summarize the design and compare the Stoughton and Whittenton Alternatives.

1.4.7.1 Stoughton Alternative Signals and Communications

The Stoughton Alternative requires a new Positive Train Control (PTC) signal system for the New Bedford Main Line, Fall River Secondary, and the Stoughton Line. Modifications to the existing NEC signal system are limited to updating the signal logic at the Canton Junction Interlocking. These minor improvements would be needed to make the signal logic on the corridor consistent with the signal logic of the new system on the Stoughton Line.

1.4.7.2 Whittenton Alternative Signals and Communications

The Whittenton Alternative requires a new PTC signal system for the New Bedford Main Line, Fall River Secondary, Attleboro Secondary, Whittenton Branch, and Stoughton Line. Modifications to the existing NEC signal system are limited to updating the signal logic at the Canton Junction Interlocking. These minor improvements would be needed to make the signal logic on the corridor consistent with the signal logic of the new system on the Stoughton Line.

1.4.8 Rolling Stock

Both the Stoughton and Whittenton Alternatives would use commuter rail technology on a fixed-guideway system with steel wheels operating on steel rails, with typically a single locomotive pulling (outbound) or pushing (inbound) a number of passenger coaches. On the MBTA system, coaches can be either single level or bi-level. Commuter rail trains would be powered by diesel or electric locomotives, depending on the alternative. The electric locomotives would be powered by a 25 kV/60 Hz overhead catenary system (OCS). The diesel alternatives would not require an OCS.

Table 1.4-8 summarizes the number of new coaches and locomotives required for each commuter rail alternative.

Table 1.4-8 Rolling Stock Requirements[1]

Alternatives	Locomotives	Coaches	Cab Cars
Stoughton	10	72	10
Whittenton	10	72	10

1 Includes spare locomotive, coaches, and cab cars since the MBTA currently does not have electric locomotives.

1.4.9 Electrification System

A new traction electrification system is required to provide electric power to locomotives for the electric commuter rail alternatives. The diesel alternatives would not require these infrastructure improvements.

The new traction electrification system would tie into the existing NEC electrification system with some modifications to that system. The traction electrification system would provide power to the trains from wayside traction power facilities through an overhead catenary system (OCS) that distributes the power

to the trains' pantographs. The pantographs, mounted on the roof of the rolling stock, would collect the electrical power from the OCS, through mechanical contact by sliding under the OCS contact wire. The electrical circuit would be completed back to the source substation via multiple return paths, including running rails and static wires.

Three major elements would make up the traction electrification system:

- Traction Power System, which include traction power substations, switching stations and paralleling stations.
- Overhead Catenary System (OCS), which distributes the electrical power to the rolling stock, and includes the messenger and contact wires, and the associated supporting structures and hardware. The track negative feeder wires are considered associated with the OCS.
- Traction Power Return System, which makes up the running rails, impedance bonds and static wires.

1.4.10 Stations

New commuter rail stations generally would consist of high-level platforms, canopies, commuter parking, and a pick-up/drop-off area for buses and "kiss & ride" that conform to MBTA Commuter Rail Station design criteria and the Americans with Disabilities Act (ADA). Stations are intended to function similarly to the majority of existing MBTA commuter rail stations; they would be unattended and would require self-pay parking. The proposed stations would not include station buildings. The locations of stations under the Stoughton and Whittenton Alternatives are shown in Figures 1.4-2 and 1.4-3, respectively. As shown in Table 1.4-9, the stations are common to both the Stoughton and Whittenton Alternatives, except for the Taunton Station (Stoughton Alternatives only) and the Dana Street Station (Whittenton Alternatives only).

Station locations have remained as shown in the DEIS/DEIR, with the exception of the Stoughton Station and Downtown Taunton Station. Stoughton Station was relocated to eliminate conflicts with traffic in Stoughton Center and to support downtown revitalization efforts. Several alternatives for the relocation of the Stoughton Station were evaluated (see Chapter 3).

Downtown Taunton Station as described in the DEIS/DEIR was replaced by Dana Street Station, due to development of the originally selected site near the GATRA bus terminal since the publication of the DEIS/DEIR. The Dana Street site was chosen as a replacement for the Downtown Taunton station site since it is a sizable vacant parcel along the right-of-way and is proximate to the previously selected Downtown Taunton site.

Table 1.4-9 Summary of Stations

Station Name	Municipality	Station Type	Parking Spaces	Platform Type[4]	Stoughton Alternative	Whittenton Alternative
Canton Center	Canton	Existing	210[1]	Side (2,Low)	x	x
Stoughton	Stoughton	Relocated	636	Side (2)	x	x
North Easton	Easton/Stoughton	New	501	Center Island	x	x
Easton Village	Easton	New	0[2]	Side	x	x
Raynham Park	Raynham	New	432	Center Island	x	x
Taunton	Taunton	New	210	Side	x	-
Taunton Depot	Taunton	New	398	Center Island	x	x
Freetown	Freetown	New	173	Side	x	x
Fall River Depot	Fall River	New	528	Side	x	x
Battleship Cove	Fall River	New	0[2]	Side	x	x
King's Highway	New Bedford	New	360[3]	Side	x	x
Whale's Tooth	New Bedford	New	748	Side	x	x
Dana Street	Taunton	New	477	Side	-	x
TOTAL – NEW STATIONS					10	10
TOTAL – MODIFICATIONS TO EXISTING STATIONS					2	2

1 Existing lot
2 Pick up/Drop off only
3 Shared parking
4 All platforms are single high-level unless denoted otherwise

1.4.11 Layover Facilities

Midday Facilities - The South Coast Rail project would require midday storage in the Boston area, anticipated to be constructed as part of the South Station Expansion Project. The South Station Expansion Project and the need for increased layover facility capacity near South Station is independent of the South Coast Rail Project.

Overnight Layover Facilities - Both of the commuter rail alternatives would require overnight layover facilities along the Fall River Secondary and New Bedford Main Line.

The DEIS/DEIR identified five alternative sites for overnight layover facilities. Church Street and Wamsutta sites were identified on the New Bedford Main Line, and the ISP Site, Weaver's Cove East, and Weaver's Cove West were identified on the Fall River Secondary. The DEIS/DEIR did not identify a preferred site on either branch. Subsequent to the DEIS/DEIR, the alternative sites were reviewed and recommended sites identified on each branch, as documented in the February 2012 Layover Facility Site Selection (provided in Appendix 3.2-E).

On the New Bedford Main Line, Wamsutta was considered the most favorable location to site a New Bedford layover facility as it has less environmental impact than the Church Street site from the perspective of land acquisition, tax revenue loss, wetlands, and hazardous materials. Wamsutta would also be operationally more efficient with its close proximity to the terminal station, saving the project roughly $500,000 annually.

On the Fall River Secondary, Weaver's Cove East was considered the most favorable location for a Fall River layover facility as it has the least environmental impacts of the Fall River sites with the fewest land acquisition requirements, wetland impacts, impacts to cultural resources and to wild and scenic rivers, and from the perspective of encountering hazardous materials. Weaver's Cove East would also be operationally more efficient than the ISP site with its close proximity to the terminal station, saving the project roughly $500,000 annually.

1.4.12 Cost

The estimated capital costs for the rail alternatives are presented as incremental funding needs over a 30-year period, a typical financing period. Capital equipment costs are presented as the incremental cost of the life of the equipment as defined by FTA guidelines. The net result of this analysis is the identification of the annual funding requirements above and beyond the costs already programmed for the horizon year (No-Build Alternative).

Table1.4-10 provides a summary of the cost estimate and analysis for the Stoughton Electric Alternative. The Whittenton Alternative would have a similar cost. Based on the O&M cost estimates developed for the DEIS/DEIR the Diesel Alternatives would be approximately 30 percent lower than the Electric Alternatives.

The Operations and Maintenance Cost (O&M) was calculated for the Stoughton Electric Alternative. This calculation was based off of updated projected service for 2030. The total amount in 2012 dollars is $33,914,000. The O&M cost for the Whittenton Alternative would be $36,210,000. The Whittenton Alternative would have a similar, but somewhat greater cost due to its increased track length. Based on the O&M cost estimates developed for the DEIS/DEIR, the Diesel Alternatives would be approximately three percent lower than the Electric Alternatives.

Table 1.4-10 Stoughton Electric Alternative Capital Cost Summary

Item	
Total Infrastructure Cost	$1,090,568,000
Real Estate Cost	$52,430,000
Professional Services Cost	$147,767,000
Contingency	$345,700,000
Vehicle Cost	$180,970,000
Total	$1,817,435,000

Notes: Total infrastructure costs were estimated in 2012 dollars.
Professional services are 13.55 percent of infrastructure costs without contingency. Professional services include Design, Permitting, Construction Phase Inspection & Project Management.
Contingencies are 31.70 percent of infrastructure costs and include Indirect Soft Costs, Mitigation Contingency, and Construction Contingency.
Escalation was calculated at 3.25percent per year per FTA criteria.

1.5 SUMMARY OF ENVIRONMENTAL IMPACTS AND MITIGATION

This section summarizes the adverse and beneficial impacts of the alternatives and the mitigation measures that would implemented for each resource category, where applicable. For additional and more detailed information on the impacts and mitigation measures, refer to Sections 4.1 through 5.0 of

the FEIS/FEIR. Table 1.5-1 at the end of this Executive Summary provides a summary of direct permanent impacts for all alternatives and resources.

1.5.1 Transportation

1.5.1.1 Ridership

Increased transit ridership is an important indicator of beneficial transportation effects of an alternative and given the purpose of the project also a measure of how well an alternative would be able to meet existing and future demand for public transportation between Fall River/New Bedford and Boston. The rail alternatives would result in 5,670 to 5,240 daily transit boardings in the South Coast region (commuter rail boardings at new stations plus existing commuter bus service boardings). Due to a faster travel time to Boston, the Stoughton Alternatives achieve greater ridership in the Southern Triangle than the Whittenton Alternatives. For example, the Stoughton Electric would have 840 daily boardings at Fall River Depot compared to 750 under the Whittenton Electric Alternative.

The Whittenton Alternatives ridership is also less than the Stoughton Alternatives because the Whittenton alignment does not include the Taunton Station, which has 670 daily boardings under the Stoughton Electric Alternative. The Whittenton Alternative station closest to downtown Taunton (Dana Street) has substantially lower ridership (320 daily boardings under the electric alternative).

1.5.1.2 Travel Times

Since New Bedford/Fall River commuters currently rely on cars and private bus services, an improved quality of service would have to provide a comparable or competitive travel time and improved reliability with respect to existing commuter options during peak commuting periods. The average commuting time by car during rush hour in 2009 was 90 minutes and travel time by car is projected by CTPS to deteriorate further to 100-120 minutes under the No-Build scenario. There would be no measurable change in travel time by car under the Build Alternatives because due to the saturated nature of the corridor, any trips that shift to rail with the Build Alternatives would be replaced and would result in no change to travel time by car. Travel time for the rail alternatives was based on rail operations analysis, which identified the segments of the rail corridors that would operate at top speed as well as segments where speed is constrained due to speed restrictions, geometry, vehicles, power mode, dwell times and number of stations and civil restrictions. Each commuter rail alternative has two overall run times: one for electric locomotives and one diesel locomotives. The primary factor differentiating the travel time performance of the electric vs. diesel option is the greater acceleration time for diesel trains.

The Stoughton Electric Alternative achieves the fastest travel times (77 minutes between New Bedford and Boston during the peak period). The Stoughton Diesel Alternative takes approximately six minutes longer than the electric alternative to travel the same route because of the additional time diesel locomotives need to accelerate from the stations.

The longer route, and the lower speed needed to maintain safety on the sharp curves in Taunton under the Whittenton Electric Alternative, results in a total travel time approximately seven minutes longer than the Stoughton Electric Alternative (84 minutes compared to 77 minutes). The Whittenton Diesel Alternative takes 6.5 minutes longer to travel from New Bedford to Boston than the Whittenton Electric Alternative and has the longest travel time of the rail alternatives.

1.5.1.3 Vehicle Miles Traveled

Reduction in vehicle miles traveled (VMT) as a result of implementing an alternative is an important indicator of beneficial effect of an alternative on the transportation system, as it enhances the transportation system by reducing travel on roadways through shifting trips from automobile to train or bus. Reductions in driving have several environmental benefits, notably cleaner air and fewer greenhouse gas emissions. Fewer cars on the road also eases congestion along highway corridors, resulting in time benefits.

The Stoughton Electric Alternative achieves the greatest reduction in regional daily vehicle miles traveled of all the Build Alternatives, approximately 54,700 VMT per day greater than the Whittenton Electric Alternative. The Stoughton Diesel Alternative has the second greatest VMT reduction, approximately 6.5 percent less than the Stoughton Electric Alternative. With the longest travel time and lowest ridership, the Whittenton Diesel Alternative is also the least effective of the rail alternatives in reducing regional VMT, although it still provides substantial benefits (reduction of 186,306 vehicle miles traveled per day when compared to the 2035 No-Build condition).

1.5.1.4 Intersection Traffic Impacts

The rail service proposed as part of each of the Build Alternatives would affect traffic patterns, particularly in the vicinity of new stations. To varying degrees, all rail alternatives resulted in traffic impacts substantial enough to warrant mitigation. Traffic mitigation measures are proposed at 35 impacted intersections under the Stoughton Alternatives and 32 impacted intersections under the Whittenton Alternatives.

Mitigation for Intersection Traffic Impacts

Traffic impacts will be addressed through mitigation measures including new traffic signals, traffic signal timing adjustment and addition of turning lanes.

1.5.1.5 Railroad At-Grade Crossing Impacts

Railroad at-grade crossings have the potential to cause traffic impacts due to excessive queuing and traffic spillback while the crossing is closed in order to let a train pass. The Whittenton Alternatives would require the largest number (50) of new or reconstructed railroad at-grade crossings. The Stoughton Alternatives would require (43) of new or reconstructed grade crossings. Traffic analyses conducted for the new or reconstructed alternatives indicated that none of the rail alternatives would result in unmitigatable impacts due to excessive queuing and spillback of traffic.

Mitigation for At-Grade Crossing Traffic Impacts

Traffic impacts will be mitigated by roadway reconfigurations and traffic flow improvements. All existing grade crossings to remain and all reactivated crossings would be equipped with new, state-of-the-art Automatic Highway Crossing Warning (AHCW) systems.

1.5.2 Land Use and Zoning

The Build Alternatives would all require property acquisitions outside existing rights-of-way to accommodate the new stations and rail infrastructure or bus lanes. The total acreage of property acquisition impacts of the Stoughton Electric Alternative (136.7 acres) and Whittenton Electric Alternative (136.8 acres) are nearly identical. The diesel versions of the rail alternatives result in 2.2

fewer acres of impact because of the lack of need for traction power substations, which would be required with the electric alternatives. Property acquisitions and compensation of affected property owners would be conducted in accordance with federal and state requirements.

1.5.3 Socioeconomics

1.5.3.1 Residential and Business Displacements

Property acquisitions associated with the Stoughton Electric Alternative would require 4 residential displacements and six business displacements. Based on average household size in the affected communities, nine persons would be relocated. Job losses are expected from business displacements resulting from acquisition of privately owned commercial buildings. Based on a review of residential and commercial property availability,[10] communities that would be impacted by residential displacements or business displacements have sufficient real estate capacity to absorb these displacements. Affected property owners would be provided compensation/relocation assistance in accordance with federal and state requirements.

The Stoughton Diesel Alternative would be comprised of the same elements as the Stoughton Electric Alternative, but would not need electrical infrastructure. The property acquisitions needed for the Stoughton Diesel Alternative are therefore 2.2 acres smaller than for the Stoughton Electric Alternative. The other effects to the social and economic environment that would result from the Stoughton Diesel Alternative (such as property acquisitions for stations, layover facilities, right-of-way, property tax revenue loss, residential and business displacements) are identical to those that would result from the Stoughton Electric Alternative.

The Whittenton Electric Alternative would require 3 residential displacements and 6 business displacements. Based on average household size, nine persons would be relocated. Job losses are expected from business displacements resulting from acquisition of privately owned commercial buildings, but are not quantifiable at this time. Based on a review of residential and commercial property availability, communities that would be impacted by residential displacements or business displacements have sufficient real estate capacity to absorb these displacements. Affected property owners would be provided compensation/relocation assistance in accordance with federal and state requirements.

The Whittenton Diesel Alternative would be comprised of the same elements as the Whittenton Electric Alternative but would not need electrical infrastructure; thus the property acquisitions needed for the Whittenton Diesel Alternative would be somewhat smaller than for the Whittenton Electric Alternative. The other effects to the social and economic environment that would result from the Whittenton Diesel Alternative are identical to those that would result from the Whittenton Electric Alternative.

1.5.3.2 Property Tax Revenue Loss

Property tax revenue losses as a result of the Stoughton Electric Alternative are estimated at $197,251 per year, in 2009 dollars; additional property tax revenue losses may result from small and/or partial acquisitions. Property tax revenue losses as a result of the Whittenton Electric Alternative are relatively less and are estimated at $181,351 per year, in 2009 dollars; additional property tax revenue losses may

[10] Online research of residential real estate property availability conducted by reviewing current listings of similar homes (based on zoning of affected properties) in the affected communities at www.realtor.com. Commercial real estate vacancy rates conducted by telephone inquiries to chambers of commerce in the affected communities.

result from small and/or partial acquisitions that were not estimated. The direct property tax revenue losses for affected communities would be insignificant as compared to the total property tax receipts for each town.

1.5.3.3 Neighborhood Fragmentation

Moderate neighborhood fragmentation is expected to result from implementation of the Stoughton Electric Alternative. Along the inactive portion of the Stoughton Line, some residential and commercial activity encroachment into the right-of-way has occurred in Stoughton, Easton, Taunton, and Raynham. The railroad has been out of service for some 50 years between Stoughton Station and Raynham Junction, and nearly 100 years between Raynham Junction and Longmeadow Street in Taunton. Over time, some neighborhoods on either side of the alignment have developed continuity across the inactive railroad bed as residents have used the alignment for pedestrian transit to neighbors or commercial districts within walking distance. Re-establishing rail service would include safety fencing along the railroad right-of-way through high-density residential and commercial districts, preventing such informal use of the railroad bed as a path. Additionally, motorists, pedestrians, and bicyclists would be temporarily delayed at at-grade railroad crossings when trains pass, potentially disrupting car-based transit between neighborhoods.

Moderate neighborhood fragmentation is also expected to result from implementation of the Whittenton Electric alternative. Neighborhood fragmentation within the Stoughton Line portion would be similar to that described for the Stoughton Alternative. The inactive Whittenton Branch has been out of service for some 50 years. However, neighborhoods on either side of the alignment do not appear to have developed substantive continuity across the inactive railroad bed, partially due to the industrial nature of parcels on either side of the corridor, and partially because portions of the corridor in residential areas are located in a cut section with steep-sided banks, wherein disposal of yard waste and other refuse (rather than pathways to promote neighborhood continuity) has been the primary use of the embankment. Motorists, pedestrians, and bicyclists would be temporarily delayed at at-grade railroad crossings when trains pass, but this effect is not expected to impact continuity among neighborhoods along the Whittenton Branch.

1.5.4 Environmental Justice

Adverse effects to environmental justice populations that would result from the South Rail project are similar for all applicable resource topics with the exception of noise and vibration. Among the rail alternatives, the Whittenton Alternatives would impact the greatest number of residences, and the Stoughton Alternatives the least. Additionally, a greater percentage of noise impacts would be experienced by designated environmental justice populations under the Whittenton Alternatives than the Stoughton Alternatives. Under all rail alternatives and on a regional level, adverse noise impacts would not be disproportionately borne by state-listed environmental justice communities. However, on the municipal level, the analysis concludes that state-listed environmental justice populations in Fall River would experience disproportionately high and adverse noise impacts as compared to non-environmental justice populations. This impact would be addressed through mitigation, specifically a combination of noise walls and building sound insulation.

Vibration impacts would be experienced across the region in both designated and non-designated environmental justice communities. Overall, adverse impacts would not be predominately borne by designated environmental justice communities under the Stoughton or Whittenton Alternatives. At the local level, designated environmental justice communities would experience a disproportionately high

share of vibration impacts in Fall River under both the Stoughton and Whittenton Alternatives. Environmental justice communities in Taunton would experience a disproportionately high share of vibration impacts under the Whittenton Alternatives. Identified mitigation measures would be able to offset these impacts. There are also benefits associated with the rail alternatives that would be recognized by all populations regardless of designation. Increased access would reduce travel times to Boston and other employment centers. Average travel time savings from Fall River, Taunton, and New Bedford are greatest under the Stoughton Electric Alternative, followed by the Whittenton Alternative which would improve travel times by 14 percent. The Stoughton Electric Alternative also represents the greatest travel time savings to colleges and hospitals. The Whittenton Diesel Alternative typically represents the least travel time savings of the rail alternatives.

The beneficial effects to environmental justice populations that would result from the South Coast Rail project vary considerably by alternative and community. Property values in environmental justice neighborhoods near stations may increase as a result of improved access to transit and subsequent TOD. If property values get too high, environmental justice populations may be priced out of their current locations. Conversely, property values in environmental justice neighborhoods along the alternative alignments may decrease as a result of increased noise from train operations. Overall, impacts to environmental justice populations due to property value changes are possible, but are too uncertain to predict precisely. Numerous factors other than transit contribute to changes in housing prices, such as the state of the national and regional economy, changes in income, inflation, tax policy and many other factors. Because the impact is speculative and the mitigation measures are beyond the authority of USACE or MassDOT to implement, no mitigation for displacement/gentrification impacts is proposed. Measures local governments can enact to preserve affordable housing in the vicinity of station areas are identified in Section 4.4.3.3.

1.5.5 Visual Resources

The overall impacts to visual and aesthetic resources resulting from improving or constructing the Build Alternatives would not vary considerably between the alternative alignments. Although all alternatives are rated with an overall moderate visual impact, each alternative alignment has at least one element with a substantial visual impact at the local level. The Stoughton and Whittenton Alternatives would substantially impact the visual character in the vicinity of the historic district and historic train depot in Easton, and in currently out-of-service segments of the Stoughton Line and Whittenton Branch for some 15 miles. Public views of the proposed 1.6-mile trestle would be limited throughout the Hockomock Swamp wildlife management area and would have a visual impact; however there is limited public access to this area. All Build Alternatives would have moderate beneficial impacts at the Fall River Depot Station due to new station construction in a developed area; the Stoughton Alternatives would have an additional moderate beneficial impact at Taunton Station. Electric alternatives would have higher visual impacts than diesel alternatives due to the electrical infrastructure requirements (i.e., overhead catenary system and the traction power facilities).

1.5.5.1 Mitigation for Visual Impacts

Generally, mitigation is appropriate where facilities are most visible and present a change to the existing visual environment, but are not outweighed by safety considerations. Mitigating impacts to the visual environment generally involves screening a facility or structure, or blending its design with the surrounding environment.

The proposed visual mitigation measures include siting and designing facilities to minimize changes to the visual landscape, and minimizing vegetation removal along the right-of-way. Mitigation measures such as screening and light minimization would be incorporated during preliminary or final design.

Screening and design methods could successfully reduce and mitigate some potential visual impacts to properties associated with the reactivation of any of the historic railroads for the South Coast Rail project. Impacts would be minimized by siting the power substations and stations where they would reduce changes to the visual landscape, and lighting has been selected to minimize night-sky impacts. However, visual impacts cannot be completely avoided for any alternative.

1.5.6 Noise

The Stoughton Electric Alternative (Stoughton, Southern Triangle - Fall River, and Southern Triangle - New Bedford segments) would result in 1,106 moderate and 341 severe impacts to residential receptors (excluding horn noise). The diesel operations would have similar impacts, with 1,085 moderate and 344 severe impacts.

The Whittenton Electric Alternative (Stoughton partial, Whittenton, Southern Triangle - Fall River, and Southern Triangle - New Bedford segments) would result in 1,232 moderate and 381 severe impacts to residential receptors (excluding horn noise). The diesel operations would have lower impacts, with 1,228 moderate and 367 severe impacts.

Train horns along the Stoughton Alternative would have 628 moderate and 689 severe impacts. The Whittenton Electric Alternative would result in the train horns producing 1,019 moderate and 1,322 severe impacts. The Whittenton alternative results in the highest railroad grade crossing noise impacts.

The No-Build Alternative would not result in any noise impacts.

1.5.6.1 Mitigation for Noise Impacts

Where sensitive land uses such as residences (as defined in the FTA guidelines) are impacted at the Severe Noise Impact Level, the MBTA will provide noise barriers or other noise measures designed to reduce the noise impact, if cost-effective. Such measures will be considered cost-effective by the MBTA if the total cost of the wall or other measure is less than $30,000 per dwelling unit, and the wall is found to be effective in reducing noise levels below the impact threshold.

The MBTA will initially evaluate the severe impact locations to determine if a noise barrier can be provided. Where noise barriers are not cost-effective by the above standard, or where noise barriers cannot provide a sufficient level of noise reduction, the MBTA will consider providing funding for building noise mitigation. The cost-effectiveness limit for building noise mitigation will be $5,000 per dwelling unit per decibel of noise impact projected above the Severe Noise Impact Level (not to exceed $30,000 total).

For the Stoughton Electric Alternative, severe noise impact locations were evaluated to identify the potential noise mitigation measures. A noise analysis was performed in order to develop the Stoughton Electric Alterative Noise Mitigation Plan (NMP) and found that a noise barrier would be the most cost-effective mitigation measure at four locations. In total, 5,500 linear feet of noise barriers costing $1.65 million are proposed for the Stoughton Electric Alternative. For the remaining severely impacted

sensitive receptor locations, building insulation is the most cost-effective noise mitigation for reducing the noise impact associated with the rail operations along the Stoughton Electric Alternative.

A detailed NMP has not been developed for the Stoughton Diesel, Whittenton Electric or Whittenton Diesel Alternatives. As these alternatives would result in noise impacts in many of the same locations as the Stoughton Electric Alternative, noise barriers similar to those described for the Stoughton Electric Alternative would likely be feasible. Building insulation would be used to address severe impacts in locations where noise barriers are not cost effective.

An option for reducing train horn noise impacts under FRA regulations (49 CFR Parts 222 and 22) would be to establish “quiet zones” at grade crossings. In a quiet zone, train operators would sound horns only in emergency situations rather than as a standard operational procedure because of safety improvements made to the at-grade crossings. Establishing a quiet zone requires cooperative action among the municipalities along the rail right-of-way, freight railroads and appropriate federal, state and local agencies. The FRA regulation also authorizes the use of automated wayside horns at crossings with flashing lights and gates as a substitute for the train horn. While activated by the approach of trains, these devices are pole-mounted at the grade crossings, thereby limit the horn noise exposure area to the immediate vicinity of the grade crossing. Although the establishment of quiet zones or the use of wayside horns would be very effective mitigation (eliminating all or nearly all horn noise impacts), considerable design analysis and coordination efforts would be required to determine their feasibility. MassDOT is not recommending quiet zones and the implementation of quiet zones is not within the control of USACE because the application to FRA must be made by the affected local governments.

Noise impacts may still be present after the NMP proposed noise mitigation measures have been finalized. Noise walls can provide a maximum of approximately 10 dBA noise reduction, and usually protect only the yards and ground level floors. Building noise insulation (soundproofing) can provide 10 to 15 dBA of additional exterior-to-interior noise reduction, but does not mitigate exterior noise and the building’s windows must remain closed to maintain effectiveness.

1.5.7 Vibration

Vibration impacts of the Build Alternatives reflect annoyance and would not rise to a level considered to cause structural damage. The vibration impacts from the Build Alternatives are similar because they follow the same track alignment for most of the corridor, except for the section between the Whittenton Branch turnout (Raynham Junction) and Weir Junction. Based on the vibration impact assessment results, the Stoughton Alternatives would impact 369 residences, while 417 residential impacts would occur under the Whittenton Alternatives. The Whittenton Alternatives result in 48 more impacted receptors, with the Attleboro Secondary segment of the Whittenton Alternatives being the primary cause of the greater impacts.

The bus services added as part of the No-Build Alternative would not generate vibration levels sufficient to cause human annoyance.

1.5.7.1 Mitigation for Vibration Impacts

The need for vibration mitigation in a specific location is determined based on the magnitude of the impacts and consideration of other factors such as feasibility and cost-effectiveness. MBTA has developed a noise mitigation policy that is consistent with the FTA guidance and establishes a cost

effectiveness criterion of $30,000 per dwelling unit. MBTA also utilizes this same cost effectiveness criterion ($30,000 per benefited receptor) for assessing potential vibration mitigation measures.

Several mitigation measures were assumed to be incorporated in the project design and were included in the vibration modeling analysis:

- Use of continuously welded rail to minimize vibrations caused by wheels impacting rail joints.
- Ballast (the crushed rock under the tracks) and sub-ballast (gravel base) will be emplaced to standard depths established by the MBTA to reduce transmission of vibration from the tracks to the ground.
- Turnouts will be located at least 100 feet away from homes and other sensitive buildings, to minimize higher vibration levels due to passage of wheels over the gap in turnout frogs.
- Trains and track will be maintained in such a manner as to minimize vibration generated by the trains, including regular wheel re-truing to eliminate wheel flats.

Additional mitigation measures, such as ballast mats (rubber mats placed under the ballast) will be provided where vibration mitigation is justified, and soil conditions are appropriate, as determined by on-site inspection of each potential mitigation location. Ballast mats, which can give vibration reductions of between 3 and 10 VdB, are very effective in attenuating frequencies of greater than 100 Hz found in vibrations near the source, and for track-receptor geometries traveling through dense soil and rock. The vibration analysis identified a total of 369 residences likely to be impacted by the Stoughton Electric Alternative. Based on the length of the ballast mat, and the cost of this mat at $180 per track foot, a mitigation price was determined for each receptor location. As discussed above, only cost-effective mitigation measures under $30,000 were considered. Of the total impacted receptors, 296 (39 locations) were considered to be cost-effective for vibration mitigation. Approximately 33,350 linear feet of ballast mat would be required along the rail corridor at a cost of approximately $6,003,000. The use of "frogs" (sections of railroad track at a switch that guide rail car wheels from one track to the other) with spring-loaded mechanisms, rather than conventional frogs, would eliminate the impact at the receptor located within 225 feet of the switch at Weir Junction.

Along shared segments, the vibration mitigation under the Whittenton Alternatives would be the same as described above for the Stoughton Alternatives (e.g. Southern Triangle and portion of Stoughton Line). For the Whittenton Branch and Attleboro Secondary portions of the Whittenton Alternatives, a total of 6,300 feet of ballast mat costing $1,134,000 was found to be cost effective for these segments.

1.5.8 Cultural Resources

The rail alternatives would all result in direct adverse effects to five above-ground historic properties, including one National Historic Landmark (specifically, the existing Old Colony Railroad Station which is part of the H.H. Richardson National Historic Landmark, located in North Easton). The electric versions of the alternatives would result in greater visual indirect effects to historic resources than the diesel versions because of the overhead electrical infrastructure and traction power substations required for the electric alternatives. The Stoughton Alternative could impact ten known archaeological sites that are eligible for the National Register (NR), compared to eleven archaeological sites under the Whittenton Alternatives.

Each of the alternatives would also have the potential to affect as yet to be determined archaeological resources and areas of archaeological sensitivity (which would require further investigation to determine if archaeological resources were present).

Based on a comparison of the results of the Intensive Archaeological Survey on the Stoughton Line between Route 138 and Weir Junction, and the Whittenton Alternatives within the same section, the Whittenton Alternatives would have greater impacts to archaeological resources recommended as eligible for the National Register.

The Stoughton Alternatives in this section would likely affect three sites: the King Philip Street Site and the Chickering Road site , and the East Brittania Street Site . Each of these sites yielded a low density of quartz chipping debris and other stone tools (a broken rhyolite point tip and an argillite cobble cortex, and a quart scraper). These three sites show evidence of stone tool manufacturing/maintenance.

The Whittenton Alternatives in this section would affect three sites near the northern end of the Whittenton Branch: the Mel's Diner Site, Brown Couch Site, and ATV Site. Each of these yielded a low density of quartz chipping debris, and one granite hammerstone. These sites appear similar to the Pine Swamp sites.

More importantly, the Whittenton Alternatives would likely affect the Cedar Swamp Site, potentially related to a known village site. The Cedar Swamp Site yielded a more complex array of pre-contact materials, including quart chipping debris, an argillite flake, a chert flake, fire-cracked rock, and a "bowl-shaped cultural feature" potentially associated with a hearth.

Based on this information, the Whittenton Alternatives are likely to have greater adverse effects to cultural resources eligible for listing in the National Register of Historic Places pursuant to Section 106 of the National Historic Preservation Act than do the Stoughton Alternatives.

1.5.8.1 Mitigation for Cultural Resources Impacts

Mitigation measures may be considered to avoid, minimize or mitigate the potential impacts on historic and archaeological resources resulting from the implementation of the South Coast Rail project alternatives. Avoidance is the preferred response when an adverse effect is determined. Adverse effects can only be avoided for the No-Build Alternative, which does not meet the project purpose. Neither of the Build Alternatives can entirely avoid direct impacts to archaeological and above-ground resources. Minimization of impact to historic properties or archaeological resources would be focused on reducing the extent of ground disturbance, establishing vegetated buffers, and designing noise barriers and sound insulation to be compatible with the historic setting, and would be addressed in the Adverse Effects documentation for each individual resource.[11]

The proposed project likely would result in unavoidable impacts to significant cultural resources that cannot be addressed through avoidance or minimization. Mitigation through data recovery and other approaches discussed below may include more than one action. The Adverse Effects documents prepared in support of the Programmatic Agreement (Appendix 4.8-A) will outline the mitigation

[11] The Adverse Effects documentation for an individual archaeological site, historic property, or district has to describe the option(s) selected to minimize impact; and has to contain a discussion about the direct/indirect effects of the option on other archaeological sites, districts, and/or historic properties in the option's Area of Potential Effect (APE). In all cases, the archaeologists and historians will have to clearly document the horizontal and vertical boundaries of the archaeological site, historic property, or district in question as part of the Adverse Effects documentation.

approaches that will be taken for each cultural resource including districts. The Adverse Effects documents are commonly referred to as Data Recovery Plans (DRP) for archaeology and Treatment Plans for above-ground historic properties. The plans would be developed after all stages of intensive (locational) survey and, as needed, evaluative testing are completed and the results of the investigations evaluated by the applicable consulting parties.

Specific mitigation commitments for cultural resources will be informed by additional, more detailed archeological survey fieldwork and additional design detail for the preferred alternative and consultation with the applicable consulting parties (including, but not limited to, federal agencies such as the Advisory Council on Historic Preservation, federally recognized Indian Tribes, and the Massachusetts State Historic Preservation Office). In general, the types of mitigation measures that will be considered for above-ground historic resources include engineering methods that reduce noise generation or vibration, and visual barriers that help to minimize aesthetic impacts. For unavoidable adverse impacts, mitigation through data recovery, treatment plans, photographic documentation or other approaches will be considered.

1.5.9 Air Quality

All alternatives comply with the Clean Air Act Amendments (CAAA) and the Executive Office of Energy and Environmental Affairs (EEA) policy on Greenhouse Gas emissions. The ozone mesoscale analysis demonstrated that the Build Alternatives would result in a decrease of volatile organic compounds (VOC) and nitrogen oxides (NO_x) emissions (precursor emissions to the formation of ground level ozone or smog), as compared to the No-Build Alternative.

The Alternatives would incorporate reasonable and feasible mitigation measures to reduce carbon dioxide (CO_2) and greenhouse gas (GHG) emissions consistent with DEP guidelines. All Build Alternatives meet the EEA policy on GHG emissions because they include mobile and stationary source mitigation measures that will reduce the GHG emission from levels expected from a project without mitigation.

1.5.9.1 Mesoscale Analysis Results

The air quality study included a mesoscale analysis that estimates the area wide emissions of VOC, NO_x, CO_2) carbon monoxide (CO), and particulate matter (PM) emissions. The mesoscale analysis calculated the 2035 mobile source emissions from the major roadways in the study area as well as train emissions.

All rail alternatives would reduce emissions of $NO_{X,}$, CO, and CO_2, in comparison to the No-Build Alternative. All of the rail alternatives have a negligible effect on particulate matter emissions. The electric alternatives all have lower emissions than the corresponding diesel alternative for all of the pollutants. This difference is most notable for NO_X, where the emissions for the electric alternative are substantially less than the corresponding diesel alternative (due to the higher NO_X output related to the locomotives burning diesel fuel). The Stoughton Electric Alternative generally results in the greatest reduction in emissions, consistent with the greatest estimated reduction in VMT.

1.5.9.2 Microscale Analysis Results

The air quality analysis evaluated the potential for impact of motor vehicles and train locomotives on hotspot locations around stations. Hotspot locations are typically congested intersections. The microscale analysis followed EPA guidelines and included motor vehicle and train emissions to calculate worst-case concentrations.

The trains that will be used on the rail alternatives could be electric or diesel. The electric trains do not emit air pollutants and will not contribute to air quality impacts on receptor locations. The microscale analysis, which typically focuses on motor vehicle emissions, added the emissions of the diesel commuter rail trains to the intersection receptor locations to calculate the highest concentrations of CO, PM_{10}, and $PM_{2.5}$ (representing a worst-case condition). All of the pollutant concentrations are below (in compliance with) the National Ambient Air Quality Standards (NAAQS). The rail alternatives would not substantially change any of the concentrations of CO, PM_{10}, and $PM_{2.5}$.

The results demonstrate that all alternatives will meet the NAAQS for CO, PM_{10}, and $PM_{2.5}$. The worst-case modeling results indicate that the alternatives will not cause any new violation of the NAAQS, increase the frequency or severity of any existing violations, or delay attainment of any NAAQS.

1.5.9.3 Greenhouse Gas Emissions

The EEA has developed a policy that requires project proponents to identify and describe the feasible measures to minimize GHG emissions. The policy requires quantification of the project's direct and indirect GHG emissions and identification of measures to avoid, minimize, or mitigate such emissions.

The air quality analysis evaluated the motor vehicle and train locomotive GHG emissions and discussed a commitment to using train engine plug-ins and electric block heaters at layover facilities. All Build Alternatives represent a GHG mitigation measure because they are all designed to reduce VMT. All Build Alternatives will reduce GHG emissions as compared to the No-Build conditions. Of the Build Alternatives, the Stoughton Electric Alternative would have the greatest GHG reduction benefit at 60,859 tons of carbon dioxide per year, followed by the Whittenton Electric Alternative at 49,490 tons of carbon dioxide per year. The diesel alternatives would be less effective than the electric alternatives in reducing greenhouse gas emissions, with the Stoughton Diesel and Whittenton Diesel reducing 2035 carbon dioxide emissions by 29,166 and 14,164 tons/year, respectively.

1.5.9.4 Air Toxics

Mobile sources emit "hazardous air pollutants" or air toxics that can cause cancer and other serious health effects. The air quality study qualitatively evaluated the potential for impact due to mobile source air toxics (MSAT).

For each alternative, the amount of MSATs emitted would be proportional to VMT, assuming that other variables such as fleet mix are the same for each alternative. The VMT estimated for each of the Build Alternatives are lower than that for the No-Build Alternative, because any of the South Coast Rail alternatives will remove vehicles (and therefore reduce VMT) from the study area roadways by shifting mode choice to public transportation (i.e. the South Coast Rail). This reduction in VMT would lead to lower MSAT emissions for the Build Alternatives. The differences in VMT between the various alternatives will result in similar differences in the MSAT emissions.

Based on an FHWA analysis using EPA's MOVES2010b model even if national VMT increases by 102 percent as assumed from 2010 to 2050, a combined reduction of 83 percent in the total annual emissions for the priority MSAT is projected for the same time period.[12] Local conditions may differ from these national projections in terms of fleet mix and turnover, VMT growth rates, and local control measures. However, the magnitude of the EPA projected reductions is so great (even after accounting for VMT growth) that MSAT emissions in the study area are likely to be lower in the future in all cases.

[12] http://www.fhwa.dot.gov/environment/air_quality/air_toxics/policy_and_guidance/aqintguidmem.cfm

1.5.10 Protected Open Space and Areas of Critical Environmental Concern

The South Coast Rail project alternatives would use existing railroad or highway alignments to the maximum extent possible, avoiding or minimizing impacts to protected open spaces. Where property acquisition of protected open spaces is necessary, direct mitigation will be required. Once the preferred alternative is selected and final design completed, such direct mitigation would be negotiated with the affected entity.

The area of protected open space and publicly owned parcels within Areas of Critical Environmental Concern (ACECs) required for improving or constructing the project is very similar among the alternatives. For all alternatives, the overall impact (0.16 acre) would be small relative to the total area of protected open space within the South Coast Rail Project area. All of the alternatives would impact considerably less than 0.01 percent of the total area of protected open space.

Legal access to protected open spaces and Areas of Critical Environmental Concern (ACECs) would not be significantly impacted by constructing, reconstructing, or using the railroad alignments, stations, or layover facilities. Current but unauthorized access to protected open space and the Hockomock Swamp ACEC via the MBTA-owned, out-of-service portion of the Stoughton Line would cease.

The No-Build Alternative would not require any new construction or land acquisition and would not directly affect protected open spaces and/or ACECs.

1.5.10.1 Mitigation for Impacts to Protected Open Space and Areas of Critical Environmental Concern

The South Coast Rail project alternatives would use existing railroad or highway alignments to the maximum extent possible, avoiding or minimizing impacts to protected open spaces. Where property acquisition of protected open spaces is necessary, direct mitigation will be required. Once the final design is completed, such direct mitigation would be negotiated with the affected entity.

1.5.11 Farmland Soils

Based on the conservative assessment used to complete the Natural Resources Conservation Service (NRCS) forms, no significant impacts are anticipated for designated farmland soils that would be altered by this project. Note that farmland soils as defined by NRCS are unrelated to the land use of the affected properties—farmland soils can exist in areas where no active farming is occurring. Impacts for each alternative to farmland soils are as follows:

- Stoughton Electric Alternative would result in impacts to 18.6 acres of designated farmland soils;
- Stoughton Diesel Alternative would result in impacts to 16.0 acres of designated farmland soils;
- Whittenton Electric Alternative would result in impacts to 18.8 acres of designated farmland soils;
- Whittenton Diesel Alternative would result in impacts to 16.2 acres of designated farmland soils

Using the USDA scoring system, impacts to farmland soils under all Build Alternatives would not be considered significant under the Farmland Protection Policy Act, and mitigation for these losses would not be required.

1.5.12 Hazardous Materials

Each of the build alternatives under consideration would require acquisition of properties with Recognized Environmental Conditions (RECs; sites with the presence or likely presence of hazardous materials) that would require further investigation. In each case, remediation or soil/groundwater management during construction could be required. The Stoughton, and Whittenton Alternatives each have at least five high impact RECs that were identified, and these alternatives also have the potential to encounter soil or groundwater contamination. Taunton Station on the Stoughton Alternatives, and Dana Street on the Whittenton Alternatives have three and one high impact RECs, respectively, that were identified. Overall, a greater number of RECs were identified for the Whittenton Alternatives (32) than for the Stoughton Alternatives (29).

The Stoughton Alternatives and the Whittenton Alternatives would have environmental benefits. Although sites containing RECs could increase construction costs, there would be an environmental benefit associated with remediating contaminated sites, particularly the station sites with known soil and groundwater contamination such as the Taunton Station site. The alternatives that would have the greatest environmental benefits are the alternatives with the most RECs (i.e., Stoughton Alternatives) since these properties are the most likely to have contaminated environmental media that would be cleaned up for the proposed South Coast Rail project.

Both layover sites would involve acquisition of properties with RECs. Five RECs were identified at the Wamsutta site, none of which are high impact RECs. Five RECs, two of which are high impact RECs, were identified for the Weaver's Cover East Site.

The spill or release of Oil or Hazardous Materials (OHM) in the process of constructing the South Coast Rail project is an unlikely event, and measures would be required to prevent and control any such spills. The construction contractors would implement a Spill Control Program in compliance with the Massachusetts Contingency Plan (310 CMR 40.0000, "the MCP") and MBTA policy. These measures would be employed both at the rail reconstruction sites and station construction sites.

1.5.13 Geology

Soil and rock affected by the Build Alternatives would be excavated and disturbed during construction. Once a Build Alternative is operational, no further potential long-term impacts to the underlying bedrock geology or soils would be anticipated due to the elements of the Build Alternatives.

None of the Build Alternatives would require tunneling or other deep excavation that would significantly affect geological conditions. Most disturbance activities would encompass a relatively small area within or adjacent to previously disturbed areas and infrastructure. These include active rail and out-of-service rail beds (Stoughton line and Whittenton Branch) that have previously been established to be compatible with subsurface conditions. No long-term changes to geologic structures or faults, to bedrock, soils, or geologic stability, to seismicity, or to the rock and soil units surrounding excavations would be expected as a result of the Build Alternatives

No specific impacts with respect to soils or geology would be anticipated under the No-Build Alternative.

No long-term adverse impacts to soils and geology would occur with any project alternatives; therefore, no mitigation will be required.

1.5.14 Biodiversity

All build alternatives would result in the loss of upland habitat, wetland habitat, and vernal pool habitat (including direct and indirect impacts to vernal pools as well as supporting upland habitat used by vernal pool amphibians). All build alternatives would also result in increased habitat fragmentation and exacerbate existing barriers to wildlife movement.

Wetland habitat loss, vernal pool habitat loss and loss of surrounding vernal pool upland habitat would all be greater under the Stoughton Alternatives (12.3, 1.43 and 43.40 acres respectively) then under the Whittenton Alternatives (11.2, and 0.8 and 41.61 acres, respectively). However, in other respects the Whittenton Alternatives would have greater impacts on biodiversity than the Stoughton Alternatives. For example, the Whittenton Electric Alternative would impact 187.98 acres of upland wildlife habitat, over 5 acres greater than the impacts under the Stoughton Electric Alternative (182.27 acres). The University of Massachusetts' Conservation Assessment and Prioritization System (CAPS) model analysis also indicates that the Whittenton Alternatives would have a slightly higher loss of Index of Ecological Integrity (IEI) Units with a total loss of 484.6 versus 474.5 for the Stoughton Alternative.

Each of the rail alternatives would result in habitat fragmentation and associated indirect effects on natural communities. The Stoughton Alternatives would exacerbate fragmentation of wetland and upland communities, particularly through the Hockomock Swamp and Pine Swamp, although the barrier effect in Hockomock Swamp would be reduced by constructing a trestle. The Whittenton Alternatives would also exacerbate fragmentation of wetland and upland communities, particularly through the Hockomock Swamp and along the Whittenton Branch, although the barrier effect would be reduced by constructing a trestle in the Hockomock Swamp.

The No-Build Alternative would not create any new impacts to natural communities or biodiversity.

1.5.14.1 Mitigation for Biodiversity Impacts

Strategies and measures that could be used to mitigate for impacts to biological diversity were evaluated. The assessment considered whether impacts to biodiversity could be avoided or minimized, and whether mitigation measures could be incorporated into the alternatives to mitigate for unavoidable impact.

The Build Alternatives use existing, active rail lines (e.g., New Bedford Main Line, Fall River Secondary and Stoughton MBTA line) where possible to reduce impacts to natural communities. Station and layover facility sites were selected to avoid impacts to sensitive biological resources. Where avoidance is not possible, impacts would be minimized to the best extent practicable. Measures to minimize direct and indirect impacts to biodiversity (plant, wildlife, and aquatic communities) will be developed as part of the mitigation for impacts to wetlands, threatened and endangered species, and water resources. In addition to other minimization measures not yet identified, these measures would include:

- Adjusting the grading to reduce the loss of plant or wildlife communities.
- Evaluating all existing culverts to determine whether replacing a culvert could adversely impact, or benefit, biodiversity.

- Installing new crossing structures within railroad grades and/or between railroad ties to facilitate safe passage of fauna across the right-of-way.

- Using retaining walls to reduce the loss of unique natural communities.

- Replanting disturbed areas.

- Developing and implementing an invasive species control plan within the Hockomock Swamp.

The Stoughton and Whittenton alternatives were designed with specific measures to minimize habitat fragmentation. Both the Stoughton and Whittenton Alternatives include the proposed Hockomock trestle, extending for approximately 8,500 feet. The trestle would maintain habitat connectivity for small terrestrial and aquatic vertebrates and other wildlife and thus minimize impacts to biodiversity. The Whittenton Alternative would further minimize impacts to biodiversity by avoiding the Pine Swamp area in Raynham, which would be crossed by the Stoughton Alternative.

Each of the alternatives presents opportunities to improve wildlife habitat, particularly by reconstructing existing culverts or bridges to improve wildlife or fish passage and reduce fragmentation. In addition, the proposed Hockomock trestle would eliminate unauthorized access to the ACEC by all-terrain-vehicles (ATVs) that have been observed leaving the right-of-way and entering adjacent vernal pools, thereby affecting sensitive (breeding, egg and larval) stages of amphibians, including rare species. The result would be a reduction in adverse effects to these communities that would otherwise continue under the No-Build condition.

1.5.15 Threatened and Endangered Species

There are no species listed on the Federal Threatened and Endangered Species Lists that would be affected by any of the alternatives.

Each of the Build Alternatives could impact eight species listed under the Massachusetts Endangered Species Act, including one salamander (blue-spotted salamander: *Ambystoma laterale*), two turtles (Blanding's turtle: *Emydoidea blandingii* and eastern box turtle: *Terrapene carolina carolina*), one freshwater crustacean (coastal swamp amphipod: *Synurella chamberlaini*), and four insects (mocha emerald dragonfly: *Somatochlora linearis*; Hessel's hairstreak butterfly: *Callophrys hesseli*; pale green pinion moth *Lithophane viridipallens*; and water-willow stem borer moth: *Papaipema cataphracta*), and would result in the loss of migratory route habitat because all rail alternatives require reconstruction of rail lines on out-of service rights-of-way where currently there are none.

The Stoughton and Whittenton Electric Alternatives would have identical impacts to the upland habitat of the Blanding's turtle (12.5 acres) and blue-spotted salamander (7.5 acres). The Whittenton Electric Alternative would have greater impacts to the upland habitat of the eastern box turtle compared to the Stoughton Electric Alternative (13.8 acres compared to 12.6 acres). The Whittenton Alternatives would also have a greater barrier effect on rare species—loss of 3.6 miles of migratory route habitat, compared to 3.2 miles under the Stoughton Alternatives. The relatively higher impacts of the Whittenton Alternatives are due to impacts along the Whittenton Branch, which includes areas surrounded by rare species habitat. The additional barrier effect of the Whittenton Alternatives is specifically attributable to potential impacts to the migration of the eastern box turtle across the Whittenton Branch.

The No-Build Alternative is not expected to create any new impacts to rare species and/or their habitat.

1.5.15.1 Mitigation for Impacts to Threatened and Endangered Species

Proposed measures to be developed in coordination with the Natural Heritage and Endangered Species Program (NHESP) to avoid, minimize and mitigate rare species impacts within the project Study Area are provided in Chapter 7. Proposed project mitigation measures for permanent impacts include:

- Construct wildlife corridors and passages through the rail bed in areas to maintain population continuity for state-listed wildlife, at the locations specified in Chapter 4.14, *Biodiversity*.
- Provide funding or land acquisition to protect up to 25 acres of land potentially used by the Hockomock Swamp population of Blanding's turtle.
- Fund a study of the Hockomock Swamp population of Blanding's turtle to assist NHESP in developing long-term protective measures, if required by NHESP in the Conservation and Management Permit.
- Provide funding or land acquisition to protect up to 11 acres of land potentially used by the Hockomock Swamp population of blue-spotted salamander.
- Provide funding to the NHESP Eastern Box Turtle Mitigation Bank equivalent to protecting up to 17 acres of habitat, or directly protect up to 17 acres of habitat through land acquisition or restriction.

1.5.16 Wetland Resources

Wetland impacts are the principal category of environmental impacts that must be considered for federal Clean Water Act Section 404 permits and variances under the Massachusetts Wetlands Protection Act. In addition to total wetland impacts, wetland fill within ACECs was also quantified, as wetlands within ACECs receive a higher level of state regulatory protection. The Whittenton Alternatives would result in direct permanent impacts to 11.2 acres of waters of the United States (including vegetated wetlands and waterbodies), compared to 12.3 acres under the Stoughton Alternatives. The impacts of the Stoughton Alternatives include some wetlands within and north and south of Pine Swamp. Both the Whittenton and Stoughton Alternatives would affect the same acreage of wetlands within Hockomock Swamp.

It should be noted that although the Stoughton and Whittenton Alternatives both cross the Hockomock Swamp ACEC, direct wetland impacts of these alternatives within this ACEC are actually quite limited (0.2 acre). This is because these alternatives would use the existing railroad grade that already crosses the swamp, which has been in existence since the late 19th Century. In fact, the actual area of impact would be on an existing stream that has overtopped its original banks (i.e. the railroad drainage ditches) and now flows over an approximately quarter-mile portion of the existing railbed.

The No-Build Alternative is not expected to create any new impacts to wetlands.

1.5.16.1 Mitigation for Wetland Impacts

Chapter 4.16, Wetlands, provides a mitigation plan to address unavoidable wetland impacts in accordance with federal and state requirements. Based on USACE requirements, permanent direct impacts of the Stoughton Electric Alternative are estimated to require 31.3 acres of compensatory wetlands mitigation—1.9 acres open water, 2.1 acres emergent wetlands, 1.8 acres scrub-shrub wetlands and 25.5 acres of forested wetlands. The Whittenton Electric Alternative would require 28.4 acres of compensatory mitigation for direct permanent impacts. The mitigation site search discussed in Chapter 4.16 also takes into consideration the mitigation requirements for temporary, temporal and secondary impacts.

A wetland mitigation site search analysis was conducted. Based on GIS analysis and agency review, the lists of sites were narrowed down to those sites with the highest potential value for wetland establishment or restoration. Based on input from the reviewing agencies, five sites were chosen from the preliminary list as having the highest potential for wetland establishment or restoration. Conceptual design was undertaken for these sites, including development of planting plans, wildlife habitat features, construction methods, invasive species control, and monitoring and reporting plans. The identified potential mitigation sites can meet the mitigation goals of the project. Specific sites will be selected by MassDOT in coordination with USACE and other agencies and the design of the selected sites advanced.

1.5.17 Water Resources

All of the Build Alternatives would have the potential to affect waterbodies and drinking water protection areas. The Stoughton Alternatives would not require construction within public water supply Zone 1 Areas (i.e. within 400 feet of the well). The Whittenton Alternatives would require construction within public water supply Zone 1 Areas (i.e. within 400 feet of the well). All of the Build Alternatives would upgrade existing transit corridors, which would have a negligible effect on pollutant loading. The Build Alternatives would upgrade existing transit corridors but would also build new rail lines on disused rail corridors, potentially introducing new pollutant sources in those areas. With mitigation and drainage features in place, none of the Build Alternatives are expected to impair any water resources.

Potential impacts to the Hockomock Swamp would occur due to stormwater discharges to Black Brook, from the Stoughton and Whittenton Alternatives. However, minimal impacts to ACECs from stormwater discharges would occur from the project. None of the above-mentioned discharges are associated with constructed stations, station platforms or parking areas. These discharges would primarily occur from conveyed overland flow from ditches along the railroad, which would carry negligible contaminant loads. None of the proposed actions are expected to impair surface or groundwater resources within the ACEC. Compliance with the Massachusetts Stormwater Management Standards is provided for all stations except Stoughton and Dana Street. Compliance will be documented for these stations (as necessary) during later project design phase phases.

1.5.17.1 Mitigation for Impacts to Water Resources

Proposed station and parking facilities for all alternatives were located on developed sites whenever possible to minimize any increases in impervious area and to avoid introducing new pollutant sources to undeveloped areas. Additional minimization measures to reduce impervious surfaces such as deck parking, the use of water quality swales, narrower streets and green "islands", a reduced building footprint, and alternative (permeable) materials for parking areas, sidewalks and roads at stations will be considered during the design stage of the project. Further minimization along the proposed transit

corridors was not possible, as the corridors themselves were determined by existing and former highway and rail alignments and could not be relocated without substantial increases in impacts to other resources.

All Build Alternatives would require specific stormwater management measures to prevent flooding and protect water quality. All stormwater Best Management Practices will meet or exceed regulatory requirements to suggest mitigation for potential impacts. These BMPs will be further refined during the design stage of the project. With the proposed mitigation measures in place, none of the Build Alternatives would be expected to substantially increase pollutant loading or impair any surface or groundwater resources.

Construction of the Build Alternatives would require a National Pollution Discharge Elimination System (NPDES) construction permit pursuant to Section 402 of the Clean Water Act. NPDES is administered in Massachusetts by the U.S. Environmental Protection Agency, and generally qualifies for a General Permit. The project would be constructed pursuant to a comprehensive Stormwater Pollution Prevention Plan (SWPPP). The SWPPP would describe potential pollutant sources on a site and dictate what best management practices (BMPs) must be implemented to manage stormwater and protect water quality during construction.

1.5.18 Coastal Zone and Chapter 91 Waterways

Depending on the alternative selected, the project is expected to require several licenses for bridges, stations and layover facilities. Additional approvals will be required for certain bridge, track and ballast improvements at existing railroad crossings of non-tidal rivers and streams. The jurisdiction of many of these crossings will be determined during further consultation with DEP and the United States Coast Guard.

The alternatives are anticipated to comply with the policies and principles of the Massachusetts Coastal Zone Management Program (MCZM). The alternatives will support water-dependent industrial uses within the New Bedford and Mt. Hope Bay DPAs by maintaining a critical transportation system supporting these uses.

Section 307(c) of the Coastal Zone Management Act of 1972 requires any non-federal applicant for a federal license or permit to conduct an activity affecting land or water uses in the state’s coastal zone to furnish a certification that the proposed activity will comply with the state’s coastal zone management program. The Build Alternatives would require a Federal Consistency Certification under the Massachusetts Coastal Zone Management Plan from the MCZM Office. It is anticipated that the alternatives would be consistent with the applicable policies.

None of the elements proposed under the No-Build Alternative are located within Chapter 91 or Coastal Zone jurisdiction. Therefore, no impacts would occur.

1.5.19 Indirect and Cumulative Impacts

1.5.19.1 Indirect Impacts

Potential indirect effects (beneficial and adverse) of the Rail Alternatives were evaluated with and without smart growth measures (including TOD). Scenario 1 considers reasonably foreseeable indirect effects from implementing the South Coast Rail project without smart growth strategies, including TOD;

while Scenario 2 outlines a future of smart growth development patterns across the South Coast region wherein housing and jobs are clustered in areas appropriate for development, while preserving important natural resource lands such as fields, forests, farmland, and wetlands.

Each of the three Build Alternatives is anticipated to induce additional growth within the South Coast Region as a result of improved transit access. However, the induced growth from each is relatively small in comparison to the No-Build Alternative, which is projected to increase the number of households by 75,212 by 2035. The Stoughton and Whittenton Alternatives would increase growth by 2,804 households over the No-Build condition, Job growth would be 1,341 greater under the Stoughton and Whittenton Alternatives by 2035 compared to the No-Build Alternative.

The No-Build Alternative and each of the Build Alternatives would result in the loss of land, including undeveloped forest land and farmland, loss of wetlands, and loss of biodiversity value. The differences among the Build alternatives are negligible. Each of the Build Alternatives would also slightly increase the effects of the No-Build baseline growth on water demand, greenhouse gas emissions, and vehicle miles traveled. The Build Alternatives would also slightly increase municipal property tax revenues as a result of new home construction.

Smart Growth

Implementing smart growth measures would not change the overall numbers of households or jobs within the Study Area, but it would re-distribute them to create compact development zones and protect undeveloped land. The savings that would accrue from fully implementing smart growth measures (Scenario 2) would be substantial in many instances. For example, the smart growth scenario would result in saving as much as 3,100 acres of farmland for the Stoughton Alternative (30 percent of the farmland loss in Scenario 1), or 12,189 acres of land (30 percent of the total in Scenario 1). The results are indicative of the benefits of the smart growth measures that could be implemented as part of the South Coast Rail alternatives. To help encourage smart growth development patterns to become reality in the future, MassDOT has developed an implementation plan for the South Coast Rail Economic Development and Land Use Plan, including performance metrics and reporting requirements (see Section 5.5).

1.5.19.2 Cumulative Impacts

Table 1.5-2 includes a summary of the incremental changes to the evaluated resources from the South Coast Rail alternatives that, in combination with past activities or trends and other known current and future projects, would potentially result in a substantive cumulative effect. Because there is no substantive difference between the impacts from rail alternatives' electric- or diesel-powered trains, these options are not included in this summary comparison. Additionally, the impacts from the Whittenton Alternative are substantively equivalent to those from the Stoughton Alternative therefore, they are incorporated in the Stoughton Alternative summary.

1.6 APPLICANT'S PREFERRED ALTERNATIVE

Section 3.3.4 provides USACE's findings with respect to the Section 404(b)(1) Guidelines. The conclusions of this section are as follows:

- The Stoughton and Whittenton Alternatives (diesel and electric variants) all meet the basic project purpose and are practicable alternatives.

- The Stoughton Alternatives (the applicant's preferred alternatives) have slightly greater impacts on aquatic resources than the Whittenton Alternatives.

- Despite having less aquatic resource impacts, the Whittenton Alternatives have other significant adverse environmental consequences and is not less environmentally damaging than the Stoughton Alternatives. Specifically, the Whittenton Alternatives have greater impacts or less benefits than the Stoughton Alternatives in the following areas:

  - Regional emissions of air pollutants (due to lower ridership and VMT reduction)

  - Habitat of state-listed threatened, endangered, or special concern species

  - Biodiversity, habitat fragmentation, and ecological integrity

  - Noise and vibration impacts to environmental justice communities due to Attleboro Secondary through downtown Taunton.

  - At-grade crossings/public safety in Taunton

- Between the Stoughton Electric and Diesel Alternatives, the Stoughton Electric Alternative is environmentally preferable due to greater reductions in regional air pollutant emissions compared to the Stoughton Diesel Alternative and no contribution to local-level air pollutant hot-spots.

The U.S. Army Corps of Engineers has therefore determined that there is no practicable alternative to the Stoughton Electric Alternative which would have less adverse impact on the aquatic ecosystem, and also does not have other significant adverse environmental consequences.

1.7 NEXT STEPS IN THE DECISION MAKING PROCESS

The FEIS/FEIR will be distributed to all agencies, officials, and public libraries that received the DEIS/DEIR, as well as organizations and individuals that provided comments on the DEIS/DEIR. Agencies, officials, and the public will be invited to submit their comments on the FEIR following publication of the FEIR and submission to the Secretary of Environmental Affairs.

Following the review period, the Corps and the Massachusetts Secretary of Environmental Affairs will consider the information in the FEIS/FEIR and the comments received. The Corps will also consider the comments received as part of the process under Section 106 of the National Historic Preservation Act. The Corps will then issue a Record of Decision (ROD), which will complete the federal environmental review process, and continue with the permitting process.

The Secretary will issue a Certificate finding whether the FEIR adequately and properly complies with MEPA and 301 CMR 11.00. If the FEIR is found to be adequate, the Secretary may specify the conditions to be satisfied in a Section 61 Finding for the project. Following the receipt of the Certificate from the Secretary, the Massachusetts Department of Transportation will prepare and issue a final Section 61 Finding.[13] A draft Section 61 Finding is included in Chapter 7 of the FEIS/FEIR. Massachusetts General

[13] Massachusetts General Laws, Chapter 30, Section 61
https://malegislature.gov/Laws/GeneralLaws/PartI/TitleIII/Chapter30/Section61

Law Chapter 30, Section 61 authorizes state agencies with permitting responsibilities to make an official determination regarding potential impacts from a proposed project and whether impacts have been avoided, minimized, and/or mitigated for appropriately. The Law requires agencies/authorities to issue a determination that includes a finding describing the environmental impact, if any, of the project and whether all feasible measures have been taken to avoid or minimize said impact. The Section 61 Finding will incorporate the results of the consultations undertaken with the Corps, the Advisory Council on Historic Preservation, and the Massachusetts Historic Commission (MHC) under both Section 106 of the National Historic Preservation Act and the State Antiquities Act (Massachusetts General Laws, Chapter 9, Sections 26 et seq.). The issuing of this finding will end the Massachusetts environmental review process during planning. Additional reviews will be performed during the permit, design and construction phases.

Following these actions, and depending on the outcome of the decision making process, the project could proceed to the subsequent stages of project development. This will include final design, permitting, equipment procurement, construction, and preparation for system operations.

Table 1.5-1 Summary of Direct Impacts

	No-Build (Enhanced Bus) Alternative	Stoughton Electric Alternative	Stoughton Diesel Alternative	Whittenton Electric Alternative	Whittenton Diesel Alternative
Description	Minor bus schedule enhancements	Electric or diesel commuter rail service to South Station using the Northeast Corridor, Stoughton Line, New Bedford Main Line, and Fall River Secondary. Ten new commuter rail stations would be constructed (North Easton, Easton Village, Raynham Park, Taunton, Taunton Depot, King's Highway, Whale's Tooth, Freetown, Fall River Depot, and Battleship Cove) and major reconstruction would occur at two existing commuter rail stations (Canton Center and Stoughton).		Variation of the Stoughton Alternative route using the abandoned Whittenton Branch right-of-way through the City of Taunton to avoid the Pine Swamp in Raynham. Ten new commuter rail stations would be constructed (North Easton, Easton Village, Raynham Park, Dana Street, Taunton Depot, King's Highway, Whale's Tooth, Freetown, Fall River Depot, and Battleship Cove and major reconstruction would occur at two existing commuter rail stations (Canton Center and Stoughton).	
Capital Cost (billions)	N/A	$1.82	$1.27	$1.82	$1.27
Operating and Maintenance Cost (millions)	N/A	$33.9	$33.8	$36.2	$36.1

2 PROJECT PURPOSE AND NEED

2.1 INTRODUCTION

On May 8, 2008, the Massachusetts Executive Office of Transportation and Public Works (EOT) (currently known as MassDOT) submitted an application to the U.S. Army Corps of Engineers under Section 404 of the Clean Water Act and potentially Section 10 of the Rivers and Harbors Act of 1899 for a Department of the Army (DA) permit to discharge fill material into waters of the United States (U.S.), ranging in area from less than 11 acres to approximately 21 acres (depending on the alternative selected), including wetlands, incidental to the construction of new public passenger rail (or other public transportation) facilities connecting the terminal stations of Fall River and New Bedford with South Station in Boston, Massachusetts (the project).

The Massachusetts Department of Transportation (MassDOT) (formerly the Executive Office of Transportation and Public Works) considered several transportation facilities and corridor alternatives to implement this transit service over a distance of approximately 50 to 60 miles. Transportation modes considered during the environmental review process included commuter rail (diesel or electric) and rapid bus.

2.2 PROJECT PURPOSE AND NEED

2.2.1 Purpose of the Project

MassDOT's stated purpose is "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, MA, and to enhance regional mobility, while supporting smart growth planning and development strategies in the affected communities." As part of its review of the Department of the Army (DA) permit application, the Army Corps of Engineers (USACE, Corps) is required to evaluate the proposal with regard to the U.S. Environmental Protection Agency (EPA) *Guidelines for Specification of Disposal Sites for Dredged or Fill Material* ("EPA Guidelines") at Title 40 of the Code of Federal Regulations, part 230. The basic project purpose is examined by the U.S. Army Corps of Engineers to determine if the project is water-dependent. A project is water dependent if it requires access or proximity to, or siting within, a special aquatic site[1] in order to fulfill its basic purpose. The USACE has determined that the basic project purpose for the MassDOT proposal is: "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts." Since ground-based public transportation does not fundamentally require siting within a special aquatic site to meet this basic project purpose, the EPA Guidelines stipulate that practicable alternatives are (1) presumed to exist and (2) presumed to be less environmentally damaging than the proposed action, unless clearly demonstrated otherwise.

The overall project purpose is used by the USACE to evaluate whether there are less environmentally damaging practicable alternatives available. The 404(b)(1) Guidelines state that an alternative is practicable if it is available and capable of being done after taking into consideration cost, existing technology, and logistics in light of *overall* project purpose (40 CFR 230.10(a)(2)). This evaluation applies to all waters of the United States, not just special aquatic sites.

[1] 40 CFR Part 230 Section 404(b)(1) Guidelines for Specification of Disposal Sites for Dredged or Fill Material Subpart E--Potential Impacts on Special Aquatic Sites.

Determination of the overall project purpose is the USACE's responsibility; however, MassDOT's needs and the type of project being proposed are considered by the USACE in reaching this determination. The overall project purpose is defined by the USACE as: "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, MA, and to enhance regional mobility. This definition is specific enough to define MassDOT's needs, but not so restrictive as to constrain the range of alternatives that must be considered under the EPA Guidelines.

For purposes of the current NEPA analysis, USACE considers and expresses the proposed project's underlying purpose and need from a public interest perspective when appropriate, but generally focuses on MassDOT's purpose and need statement. The Council on Environmental Quality (CEQ) regulations at 40 CFR 1502.13, stipulate that the EIS purpose and need statement "shall briefly specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." The USACE exercises independent judgment in defining the purpose and need for the project from both MassDOT's and the public's perspectives. The purpose and need as independently determined by the USACE is: to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts, and to enhance regional mobility.

2.2.2 Need for the Project

2.2.2.1 Transportation Problems in the South Coast Region

The current transportation system connecting Southeastern Massachusetts (i.e. the South Coast region including the cities of Fall River and New Bedford and the area served by the Southeast Regional Planning and Economic Development District [SRPEDD]) with Boston and internally is primarily a highway system and characterized by a lack of transportation mode choice, especially public transit. The highway system is composed of major, limited access state routes, regional highways, and local roadways (Figure 1.2-1). As the population in the South Coast region and employment in the Boston area have grown, the demands on the roadway system linking Southeastern Massachusetts to Boston and the rest of the region have increased, as reflected by increased traffic volumes. The increase in traffic volumes has resulted in roadway congestion and travel delays, especially during peak hours that have become worse over the past decade. The increased volume of traffic and congestion have also adversely affected air quality (contributing to air quality conditions in the South Coast region that do not meet federal Clean Air Act standards) and traffic safety. Based on the Commonwealth's forecasts, regional growth and the trend of commuters to locate to areas further away from the Boston metropolitan core, such as the South Coast region will continue to increase the demand for transportation in the South Coast region.[2] This would exacerbate the current problems of congestion, delays, transportation safety and air quality and affect an increasing number of people. A more detailed discussion of the problems identified above, as well as other considerations, is provided in Sections 2.2.2.1 through 2.2.2.10 below.

2.2.2.2 Potential Solutions to the Problem

In consideration of the above, MassDOT has determined that improving the transportation system (facilities and services) in the South Coast region is necessary to address the transportation issues facing the region.

[2] CTPS January 28, 2011 Memo "South Coast Rail Work Trips to Boston," provided in Appendix 2.2-A.

Although important investments in regional transportation facilities and services are planned, these will primarily address localized congestion or safety concerns, or repair aging infrastructure. They would not fundamentally address the lack of regional mobility and service quality.

Expansion of transportation capacity in the South Coast region with the existing transit services (bus, taxis, park-and-ride and vanpool) is limited as they use the same roadway system and are thus subject to the same roadway congestion. Transportation system solutions based on highway improvements are limited due to policy considerations and constraints imposed by the physical conditions of the metropolitan Boston area, where such highway improvements would need to be implemented to be effective in addressing capacity and congestion issues.

However, while highway expansion and utilization of existing transportation services do not provide long-term solutions to the transportation problems, MassDOT has determined that enhancement of (currently inadequate) public transit connections (in terms of travel time, service frequency, capacity and geographic availability) *does* provide opportunities to improve transportation between New Bedford/Fall River and Boston and between South Coast cities (New Bedford, Fall River, Taunton). MassDOT therefore proposes enhancement of public transit connections (collectively known as the South Coast Rail project – see Figure 1.4-1) to improve transportation between New Bedford/Fall River and Boston and between South Coast cities. Various alternatives are under consideration to enhance public transit service (using different transit modes and corridors), and these are described in Chapter 3, *Alternatives*.

The proposed public transit enhancements are consistent with the transportation goals and objectives set forth in the regional transportation plans specifically created by the Metropolitan Planning Organizations (MPOs). The long-term transportation plans of the region support the development of transportation improvements that enhance accessibility, increase mobility, encourage alternatives to automobiles, and provide a more equitable distribution of transit services.

The following describes in greater detail the need for the project and aspects that relate to regional mobility and quality of service:

- Inadequate capacity of the existing transportation system to downtown Boston
- Congestion of the roadway system
- Lack of regional mobility
- Safety issues associated with the existing roadway system
- Air quality issues associated with the existing transportation system
- Demand for transportation services
- Inadequate public transit services
- Absence of other regional transportation improvements to address the identified transportation needs
- State and local public policy context

- Smart Growth considerations

A discussion of each of the above problems is provided below. A more detailed discussion of existing and future deficiencies of the transportation system (including key factors listed above), especially as it relates to existing and future transportation demand, is provided in Chapter 4.1, *Transportation*.

Inadequate Existing and Future Capacity of the Transportation System from the South Coast Region to Downtown Boston

The existing transportation system serving the South Coast region has inadequate capacity, leading to lack of regional mobility, between the South Coast region and Downtown Boston and within the South Coast region itself. This is due in part to the relative dearth of public transit connections between New Bedford/Fall River and Boston and between South Coast cities (New Bedford, Fall River, Taunton and others). An overview of the existing transportation system deficiencies is provided below. A more detailed discussion is provided in Chapter 4.1, *Transportation*.

Roadway System Capacity and Regional Growth

The South Coast region is served by a network of roadways varying from limited access facilities to local roads. The primary highway facilities link the major urban areas of New Bedford, Fall River, and Taunton with each other and to the metropolitan Boston region. Highways provide the primary access routes within the South Coast region and to adjacent regions. The main highway facilities in the South Coast region are Route 24, Route 140, I-195, and I-495 (Figure 1.2-1). Together, Routes 24 and 140 link New Bedford and Fall River to the metropolitan Boston region. The two interstate routes (I-95 and I-495) serving the South Coast region are not part of the primary highway access system to the metropolitan Boston region. Interstate I-195 provides east-west access across the region, connecting Cape Cod, Wareham, New Bedford, Fall River, and Providence, while I-95 just west of the region connects Providence with greater Boston. I-495 runs northwest-southeast, connecting Cape Cod, Wareham, and Taunton. The only option for traffic generated within the South Coast region to reach downtown Boston are I-93/Route 128 and I-93/Route 3 (Southeast Expressway). Route 128 is Boston's inner circumferential highway which provides access to much of the metropolitan Boston region. Following I-93 north/Route 128 south from Route 24 leads to I-93/Route 3 (Southeast Expressway) and downtown Boston, approximately 8 miles from the I-93/Route 128/Route 3 interchange in Braintree. Following I-93 south/Route 128 north from Route 24 leads to I-95 approximately 3 miles to the north and to I-90 approximately 15 miles to the north. The Massachusetts Turnpike (I-90) provides the only limited-access highway to Boston from west of the city.

Both Route 128 and the Southeast Expressway are heavily congested roadways, particularly during peak periods. Traffic volumes on Route 128 are approximately 135,000 vehicles per day north of Route 24 (towards I-95) and 167,000 vehicles per day to the south (towards I-93/Route 3). Traffic volumes on I-93/Route 3 are as high as approximately 191,000 vehicles per day. On Route 24, the major north south corridor in the South Coast region, the average daily traffic ranges from 26,700 vehicles per day in Fall River to over 115,000 vehicles per day in Randolph. Traffic congestion and long delays are common on the northern segments of this highway during weekday peak commuting periods.

As the population in the South Coast region and employment in the Boston area have grown, the demands on the roadway system linking Southeastern Massachusetts to the rest of the region have increased. Traffic volumes on the limited-access state routes linking the South Coast region to the employment centers of Boston have been growing over the past decade, as shown in Chapter 4.1,

Transportation, Table 4.1-9: Average Daily Traffic Volume Growth. Overall, traffic volumes on the roadways in the South Coast region have grown at an annual rate of two to three percent over the past decade. However, traffic volumes have grown even more rapidly in some areas. The largest increases in traffic volumes have been on Route 24 in Raynham and Taunton, where the traffic volumes have had annual increases of 4.1 and 5.0 percent respectively. Traffic volumes on Route 140 in Taunton have been increasing at an annual rate of 2.2 percent. Route 128 and I-93 (the Southeast Expressway) exhibit relatively stable traffic volumes, reflecting the fact that they are already some of the most congested highways in the state and traffic volumes on these roadways are at or near capacity for long portions of the day, and have limited capacity for further increases in average daily traffic volumes leading to further congestion with continued population growth. The minor decrease in traffic on portions of I-93 may reflect changes in motorist route choices due to Central Artery/Tunnel project construction, and demand reductions from the Route 3 corridor due to the restoration of the Old Colony Commuter Rail service.

2.2.2.3 Congestion of the Roadway System

The increases in traffic volumes on the principal highways linking the South Coast region to downtown Boston have led to deteriorating level of service (LOS) on these roadways, especially during peak periods. Delays on these roadways are now common and have become worse over the past decade. These delays are especially prevalent on Route 24 as it approaches Route 128/I-93 in Randolph. Increases to peak-hour volumes of up to 3,500 and 4,000 vehicles per hour on Route 24 and on I-93/Route 128 in Braintree and in Randolph, respectively, have led to deterioration of LOS down to F on these major roadways, which are intended to relieve the local roadways from regional traffic. Several mitigation measures have been implemented on I-93 to reduce congestion (HOV lanes, improved MBTA Red Line service, and Old Colony Commuter Rail service). However, this highway continues to operate at poor levels of service, resulting in substantial congestion and decreased safety. There are no roadway alternatives to the use of Route 24 and I-93, and no mitigation measures are planned to reduce congestion.

The lack of adequate capacity of the roadway system and the resultant reduction in LOS is anticipated to become even more problematic with the increased demand for transportation resulting from the growth of the South Coast region, especially as commuters living near Boston are moving away to areas further from the metropolitan core. Southeastern Massachusetts has been one of the fastest growing areas in the Commonwealth. Between 1960 and 2000, this area experienced a growth rate of 31 percent. Between 1960 and 1990, this area had an annual growth of over 2,500 people per year from a base population of 343,353 to its 1990 population of 430,846. Growth slowed somewhat between 1990 and 2000, to an annual growth of approximately 1,950 people per year. These figures translate to a growth of 4.5 percent between 1990 and 2000. Each 10,000 new residents coming into the area are expected to generate a need for 3,500 new residential units, and are predicted to generate 27,650 new vehicle trips per day, further degrading the LOS provided by the regional transportation system. As described in greater detail in Chapter 4.1, *Transportation*, the level-of-service of the roadway system connecting the South Coast region to Boston will deteriorate even further, resulting in a concomitant increase in congestion, accidents, travel time and air pollution; not only on the highways themselves but potentially also on nearby local roadways that may absorb the traffic spillover from nearby congested highways.

2.2.2.4 Lack of Regional Mobility

The lack of regional mobility is reflected by poor connectivity between the South Coast Area and Boston. While GATRA and the Southeastern Regional Transportation Authority (SRTA) do provide intraregional transit service, there are only a limited number of one-seat transit rides from one municipality to another within the South Coast region and adjoining regions, as discussed in greater detail in Section 2.2.2.7. In this regard the South Coast region is severely underserved relative to other comparable regions, especially those that have a commuter rail system.

Of all regions in the Commonwealth, the South Coast region by this measure has the lowest regional mobility index. This is partially due to the absence of commuter rail, which in other regions provides intra (within) regional connectivity (mobility), partially as a byproduct of interregional connectivity with Boston. Chapter 4.1, *Transportation* provides a discussion of interregional links and regional mobility (Table 4.1-47).

In contrast with commuter rail services in other regions that have multiple stops along transit lines, existing express bus services within the South Coast region are by necessity limited to a few stops in order to realize a total travel time competitive with commuting by automobile. Serving additional communities with the bus services would substantially slow service to unacceptable levels, which would result in fewer transit riders. The second constraint that limits intraregional connections is bus capacity. In order to attract riders, existing bus services seek to minimize headway (maximize frequency) while operating at or near capacity almost from their initial point of departure, with very limited or no intermediate stops within the South Coast region. Existing bus services thus operate as exclusive routes with few in-between stops and thus do not provide substantial interregional connectivity.

2.2.2.5 Safety Issues Associated with the Existing Roadway System

The number of accidents on the primary travel routes within the South Coast region has generally been increasing over the past years, as described in detail in Chapter 4.1, *Transportation*, and in the accident tables included with Appendix 4.1-B. Projected future growth in traffic volume on the principal South Coast region roadways cannot be sustained by the current regional transportation system. Recurrent traffic congestion is becoming a more significant problem for the region, as is the increasing frequency of traffic accidents, especially along congested roadway corridors. Traffic volume increases may thus contribute to increased risk of injury and property damage for the commuting public.

2.2.2.6 Air Quality Issues Associated with the Existing Transportation System

Motor vehicles are the predominant sources of ozone precursor emissions within the South Coast region, which has been classified as a Severe Non-Attainment Area for ozone, which means that the region does not meet one or more of the National Ambient Air Quality Standards for the ozone, one of the criteria pollutants designated in the Clean Air Act. Automobiles also emit carbon monoxide through the partial combustion of carbon-containing compounds in gasoline. Reducing greenhouse gas emissions is a priority for the Commonwealth and the United States. Federal and State agencies such as EPA, USDOT, the Massachusetts Executive Office of Energy and Environmental Affairs and MassDOT[3] are

working to reduce greenhouse gas emissions from motor vehicles and fuels through several initiatives, including efforts to promote public transit, multi-modal systems and transit-oriented development. As discussed previously, and described in greater detail in Chapter 4.1, *Transportation* and Chapter 4.9, *Air Quality*, the highways serving the South Coast region convey high volumes of automobile traffic, and have high levels of congestion (both of which increases vehicle emissions). Transportation alternatives for South Coast commuters that would reduce the mobile-source emissions of greenhouse gases are limited due to the inadequacy of the transit system. A shift in travel from automobiles to public transit could reduce vehicle emissions and improve regional air quality.

Vehicle Miles Traveled (VMT) measures the extent of motor vehicle operation or the total number of vehicle miles travelled within the study area on given day. It is an important gauge for air quality and Greenhouse Gas emissions, as emissions of air pollutants and greenhouse gases is related to the distance traveled by automobiles (and to a lesser degree congestion). Regions with high VMTs per capita have a greater potential for poor air quality and GHG emissions compared to regions with lower VMT per capita. One of the reasons for the relatively high VMT in the South Coast region is the much greater proportion of transportation by car versus rail or bus, as compared to other regions. Daily regional automobile VMT is expected to grow from 109,926,000 under existing conditions to 118,894,000 by 2035 under the No-Build Alternative (based on updated modeling conducted by CTPS in 2012, see Appendix 3.2-I).

2.2.2.7 Demand for Transportation Services

Southeastern Massachusetts experienced a 4.5 percent population growth between 1990 and 2000. Growth slowed between 2000 and 2010, with an overall population increase in the South Coast Region of 2.9 percent. Factors driving growth in the region include the desire for affordable housing outside the Boston metropolitan area. Many of the people relocating to the area are retaining their jobs in the Boston market and thus increase the demand for transportation services between the area and Boston, as well as within the South Coast region. The number of commuter trips between the South Coast region and Boston was 8,000 in 2000 and is expected to increase by 1,200 to 9,200 in 2030.[4] Most of the commuter trips from the region to the Boston market are in single occupant vehicles and public transit accounts for a minor proportion of work trips in the service area. MassDOT expects this trend to continue in absence of improved public transit connections between Boston and the South Coast region.

2.2.2.8 Inadequate Public Transit Services

The inadequacy of public transit service in the South Coast region is reflected in several aspects: The *availability* of public transit service in absolute terms and compared to other regions, especially those that have a large commutation segment to downtown Boston, and the *quality* of transit service as expressed in travel time and frequency of service, especially during the peak hours. The geographic availability of transit service to people in the region is also relevant in terms of access to employment opportunities and services, including education and healthcare. In addition to transit services between the South Coast region and Boston, transit services within the South Coast region are also relevant. An indicator of quality of transit service is the MBTA's *Service Delivery Policy.* This policy identifies minimum frequency of service levels that provides the guidelines by which the MBTA maintains accessibility to the transportation network within a reasonable waiting period. The minimum frequency of service standards is the minimum frequency that must be maintained in a service. For Commuter Rail and

[4] CTPS January 28, 2011 Memo "South Coast Rail Work Trips to Boston", provided in Appendix 2.2-A.

Commuter Bus minimum frequencies should provide three trips in a peak direction during the AM and PM peak periods.

Existing transportation in the South Coast region is predominantly auto-oriented and transit services within the South Coast region are limited to bus and demand-response services operated by regional transit authorities and private carriers (Figure 2.2-1). Most of the commuter trips from the South Coast region to the Boston market are in single occupant vehicles and public transit accounts for a minor proportion of work trips in the service area. To a large extent, this can be attributed to the lack of public transit alternatives other than privately-operated bus service. As discussed below, many communities in the South Coast region lack public transit facilities other than private bus services and major population centers are as much as 25 miles from existing commuter rail stations. All commuter rail stations are located outside the South Coast region and are already nearing capacity.

Bus Service

Local bus public transit within the South Coast region is provided in Taunton by GATRA and in New Bedford and Fall River by SRTA. GATRA also operates intercity bus service between Taunton and Providence, Rhode Island.

Bus service to Boston from the South Coast region including the cities of Taunton, Fall River and New Bedford is limited to private carriers. Private carriers also connect Fall River, New Bedford, and Taunton with each other and with Providence, Newport, and points beyond. Bus service from the South Coast region to Boston uses the regional roadway system and is thus subject to the same congestion and safety problems on the highway system as other vehicles, resulting in long and unpredictable travel times. The bus service is also substantially more expensive than MBTA commuter rail services over similar distances, creating an additional constraint on usage of bus service, especially for lower income travelers. Some bus service exists to commuter rail stations outside the South Coast Area; however the transfer between two transit services increases overall travel time, rendering it less attractive. The private express bus service is subject to the same congestion.

While the current bus service plays an important role, especially as it is the only regular transit service between the South Coast region and Boston, its use is limited, reflecting constraints related to travel time, service frequency and cost. A summary of bus service between the South Coast Area and Boston is presented below. A more detailed description of bus service is provided in Chapter 4.1, *Transportation*.

Vanpools/Carpools

Vanpools in communities of the South Coast region are provided through MassRides, a program of MassDOT. Although relevant as a complementary service vanpool and carpool travel times are severely impacted by slow travel speeds on the expressway and secondary roads.

Park-and-Ride

Park-and-ride facilities and carpool/vanpool services are offered along the primary regional travel corridors in the South Coast region. Park-and Ride lots are associated with car-pooling, van-pooling or private bus service to Boston. There are nine public park-and-ride lots located in the South Coast region, of which five are located along the primary roadways from the region to the Boston metropolitan area and four not in the immediate vicinity of the primary access routes to Boston. In addition, three private park-and-ride lots in the South Coast region are available exclusively for customers using the private bus services to Boston. Three public park-and-ride lots are outside the South Coast region, but still along the

Route 24 access corridor to Boston. An overview of Park-and-Ride Facilities is presented in Chapter 4.1, *Transportation*. Park-and-ride facilities as feeders for bus and car-pooling and van-pooling services are limited in their effectiveness as a transportation connection with Boston, due to the inconvenience of transfers and travel times associated with the congested roadway system, both in terms of traveling to the Park-and-ride facility and travel from the Park-and-Ride facility to Boston.

Commuter Rail

Many communities within the South Coast region do not currently have commuter rail service. The nearest commuter lines (MBTA's Providence Line and Middleborough Lines) terminate on the northwest and northeast edges of the South Coast region. Starting in May 2013, MBTA, in cooperation with the Cape Cod Regional Transit Authority, established a seasonal weekends-only service known as the Cape Flyer, extending the Middleborough line from its current terminus in Middleborough to Hyannis. However, this service is limited to three round-trips per week, all on weekends, and thus serves weekend tourists rather than daily commuters between Boston and the South Coast. In fact, the three major cities in the South Coast region: Taunton, Fall River, and New Bedford are the only cities within 50 miles of Boston that are not served by passenger rail. The closest commuter rail stations to the South Coast region are Middleborough/Lakeville (MBTA Middleborough Line), and Attleboro Station and Providence Station (MBTA Providence Line). The Middleborough Line serves areas east of the South Coast region and southeast of Boston, with stations in Lakeville and Bridgewater, while the Attleboro/Providence and Stoughton lines serve communities to the north and west of the South Coast region. The Attleboro and Mansfield stations are the primary access points on the Attleboro/ Providence Line. The Stoughton Station serves as the primary access point on the Stoughton Line. All communities in the heart of the South Coast region are outside a 6-mile access radius of these stations, and some—including major population centers such as New Bedford and Fall River (combined population of 182,000)—are more than 20 miles and up to 25 miles from the nearest train station (Table 2-1).

Table 2-1 Proximity of South Coast Communities to Commuter Rail Service

Community	Closest Station	Proximity[1] (miles)
Acushnet	Middleborough/Lakeville	15.7
Berkley	Middleborough/Lakeville	10.7
Dartmouth	Middleborough/Lakeville	20.9
Dighton	Middleborough/Lakeville	13.7
Easton	Stoughton	5.1
Fairhaven	Middleborough/Lakeville	22.5
Fall River	Middleborough/Lakeville	19.6
Freetown	Middleborough/Lakeville	10.8
Lakeville	Middleborough/Lakeville	3.3
Mattapoisett	Middleborough/Lakeville	19.4
New Bedford	Middleborough/Lakeville	20.8
Norton	Mansfield	5.7
Raynham	Bridgewater	7.5
Rehoboth	Attleboro	8.8
Rochester	Middleborough/Lakeville	13.7
Somerset	Providence	19.4
Swansea	Providence	15.5
Taunton	Middleborough/Lakeville	9.7

Westport	Middleborough/Lakeville	28.3

1 Proximity measured to population centroid
Source: Google Maps

Due to their distance to the nearest commuter rail station the existing commuter rail lines to Boston are difficult for residents to access, especially for those living in Taunton, Berkley, Freetown, Fall River, and New Bedford. Travel to these stations is also limited to local secondary roads, which further increases travel time.

For those commuters in the South Coast region who live closer to commuter rail stations outside the South Coast region, constraints to the usage of the existing stations are posed by station parking and system capacity issues. Commuter rail services are currently approaching capacity and system capacity is limited due to the lack of adequate parking at these stations. Commuter rail parking lots in Attleboro, Mansfield, Stoughton, and on the Middleborough Line are already heavily utilized , as described in Chapter 4.1, *Transportation*, and are either unable or will not be able to handle any more growth. In addition, some peak hour trains experience heavy passenger loads, which was especially evident before the 2009 economic downturn. Therefore, the existing commuter rail service, although within reach of some communities in the South Coast region, is not sufficient to handle the anticipated growth in ridership. A detailed discussion of ridership forecasts is provided in Chapter 4.1, *Transportation*. Growth projections are presented in Chapter 4.3, *Socioeconomics.*

Poor or limited transportation opportunities also constrain access by South Coast region residents to important Boston destinations, including education opportunities provided by numerous private and public colleges and universities, the highest concentration of medical facilities and specialties in the Commonwealth, cultural facilities, and sporting events. Existing highway congestion, extended travel times, and limited (and often expensive) parking affect the ability of many area residents to access these destinations.

The City of Boston continues to provide substantial employment opportunities at all levels, and also contains a substantial employment labor force. Many of the South Coast region communities, particularly in the towns of Easton, Raynham and Taunton, have a substantial work orientation to Boston. Access between South Coast region communities and downtown Boston is constrained by the limited, overloaded highway system and the lack of alternative transit modes. The ability to park in Boston is constrained by the limited space available to provide parking, high demand for parking resulting from new development, the high cost of parking, and the metropolitan area parking freeze. Residents of South Coast region communities would benefit substantially from improved employment access and reduced cost of commuting and parking.

In sum, commuter rail service currently does not extend into the South Coast region, making access to commuter rail difficult for area residents.

2.2.2.9 Absence of Other Regional Transportation Improvements to Address the Identified Transportation Needs

Local communities, regional planning agencies, and MassDOT are pursuing a number of transportation and development projects within the study area. They are included in the long-range transportation plans and Transportation Improvement Programs of the Boston Metropolitan Area Planning Council (MAPC), Old Colony Planning Council (OCPC), and the SRPEDD. While important to the transportation system of the South Coast region, MassDOT has indicated that these programmed projects will not meet

the transportation needs of the region, as it relates to the inadequate capacity of the existing transportation system to Downtown Boston.

2.2.2.10 State, Regional and Local Public Policy Context

The South Coast Rail project is proposed by MassDOT as part of a comprehensive effort to achieve a series of broad study area transportation and development goals, as well as specific objectives for improving the quality of transportation services and the equity of the distribution of services within the South Coast region. These goals and objectives have been developed by MassDOT over several decades as part of both broad-based policies and specific regional documents and include the following statewide plans and reports:

GreenDOT Policy Directive (2010)—MassDOT will promote sustainable economic development, protect the natural environment, and enhance the quality of life for all the Commonwealth's residents and visitors by reducing greenhouse gas emissions, promoting the healthy transportation options of walking, biking and public transit and supporting smart growth development.

South Coast Rail Plan for Action (2007)—This report identified the South Coast of Massachusetts as one of the fastest growing regions in the state, and stated that restoration of passenger rail service could be a catalyst for economic development and job growth in the region. The plan also stated that the project would reach under-served populations and promote smart growth.

MBTA Program for Mass Transportation (2003, 2010 Draft Update[5])—This state program identifies mass transit needs through the year 2030 that would require capital expenditures and includes commuter rail service to New Bedford and Fall River.

Toward a New Growth Policy for Massachusetts (1977)—This report encouraged redevelopment of older urban areas across the state. Both New Bedford and Fall River are older urban areas seeking economic development opportunities. The two cities are designated as both federal and state economic target zones. Second, the Southeastern Massachusetts area provides affordable housing opportunities for professionals working in the metropolitan Boston area.

Boston Transportation Planning Review (1970-1973)—This program re-examined the highway construction program in the Boston area and established a new transportation strategy with a strong emphasis on transit as a means to provide additional transportation capacity into Boston.

In addition to statewide plans, regional transportation goals provide a basis for evaluating options for improvement of transportation services and facilities in the South Coast region. They support improvements to transportation services, increase mobility, provide transit services that are cost-effective, and provide a more equitable distribution of transportation benefits. Their objectives are consistent with those of the proposed project and their locally adopted goals and objectives support the broad, long-term study area development and transportation strategy, as described below.

New Bedford/Fall River/Taunton Region—The SRPEDD has adopted a multi-level set of transportation goals and objectives in the region's 2007 Regional Transportation Plan. This planning document includes goals and objectives in support of the region's overall goal of developing and maintaining an effective, safe, and accessible transportation system that promotes sustainable economic development and

[5] http://www.ctps.org/bostonmpo/4_resources/1_reports/1_studies/3_transit/pmt.html.

preserves the region's quality of life. The plan specifically states that continued support for extending commuter rail service to Taunton, Fall River, and New Bedford helps achieve these goals.

Brockton Region—The OCPC has adopted a multi-level set of transportation goals and objectives in the region's 2007 Regional Transportation Plan. This planning document includes 14 goals and objectives in support of community vision, including smart growth principles and a transportation system that is regionally coordinated and based on effective transportation and land use planning.

Boston Region—The MAPC adopted eight visions and corresponding policies in their 2007 Regional Transportation Plan. These goals and policies are based on a vision for the region that emphasizes the maintenance, management, and operation of a multimodal transportation system that provides a high degree of mobility for all people and supports the reduction of air quality degradation and other environmental degradations caused by transportation.

2.2.2.11 Smart Growth Considerations

Smart Growth as proposed by MassDOT integrates two needs identified by the South Coast region that are related to transportation: economic development and environmental preservation.

Southeastern Massachusetts has been the fastest growing region in the Commonwealth for many years both in terms of population and housing units. At the same time, population and housing growth has been unevenly distributed, with the historic cities of Fall River and New Bedford experiencing a decline in population and economic vitality while exurban areas have been experiencing development sprawl resulting in the loss of farms, fields and forests and damages to the character of the historic villages and cities within the region. There is a need for smart growth planning within the region to address the adverse effects of sprawl resulting from current and projected further uncontrolled growth and loss of open space.

The poor connectivity to the metropolitan Boston area may constrain economic activity in the urban areas of New Bedford and Fall River, which in 2006 had substantially higher unemployment rates (8.2 to 8.6 percent) than the state average (5 percent) at that time. The 2009 economic crisis further exacerbated this trend with unemployment rising to 12.4 to 12.6 percent by August 2009 in New Bedford and Fall River, respectively, compared to a statewide average of 9.1 percent. According to MassDOT, improved access to employment markets in Boston could provide employment opportunities for the New Bedford and Fall River labor force that could provide economic benefits for these communities. Commuter rail service could also allow limited "reverse commutes" from area communities like Taunton to New Bedford and Fall River, which would thereby gain access to a larger labor pool within the Southeastern Massachusetts region.

MassDOT's intent is for the South Coast Rail project to provide opportunity to generate new economic development and to shape this growth so that the project helps preserve environmental resources. The project is proposed to be implemented by MassDOT in partnership with municipalities. The transportation project would be planned by MassDOT in conjunction with local land use planning to help cluster people and jobs near transit facilities. The intent of the transportation project proposed by MassDOT would be to help open up new economic development opportunities, while directing growth away from natural areas and reducing sprawl. A discussion of future growth is provided in Chapter 4.2, *Land Use and Zoning*, and Chapter 4.3, *Socioeconomics*. A discussion of Smart Growth as proposed by MassDOT is provided in Chapter 5, *Indirect Effects and Cumulative Impacts*, which describes how

MassDOT through its Smart Growth policies seeks to reduce indirect effects and cumulative impacts on the environment.

2.3 PURPOSE AND SCOPE OF THE ENVIRONMENTAL IMPACT STATEMENT/ ENVIRONMENTAL IMPACT REPORT

This document has been prepared to comply with the requirements of NEPA, the CEQ regulations for implementing NEPA, [Title 40 CFR Parts 1500-1508], and the USACE Regulatory Program NEPA implementing regulations at Appendix B to 33 CFR Part 325. On May 7, 2008, the USACE determined that an EIS is required for this proposed project because of the project's potential to significantly affect the quality of the human and natural environment. The purpose of this EIS is to assess the environmental impacts associated with the construction and operation of transit enhancements between Fall River / New Bedford and Boston proposed by EOT.

Pursuant to its responsibilities under Sections 10 and 404, the USACE, therefore, has a responsibility to review permit requests seeking authorization to (1) perform work or build structures in the navigable waters of the United States and/or (2) discharge dredged or fill material into all waters of the United States. The USACE review considers MassDOT's purpose and need from a public interest perspective. The public interest determination involves more than an evaluation of impacts to the aquatic environment. Once the project has been determined to comply with the EPA Guidelines, the project must also be evaluated to ensure that it is not contrary to the public interest. There are 20 public interest factors listed in 33 CFR 320.4(a) (1). A project may have an adverse effect, a beneficial effect, a negligible effect, or no effect on any or all of these factors. The district must evaluate the project in light of these factors, other relevant public interest factors, and the interests of MassDOT to determine the overall balance of the project with respect to the public interest. The EIS provides the basis for this public interest review, as outlined in Title 33 CFR Part 320.4, which states:

> The decision whether to issue a permit will be based on an evaluation of the probable impacts, including cumulative impacts, of the proposed activity and its intended use on the public interest. Evaluation of the probable impact which the proposed activity may have on the public interest requires a careful weighing of all those factors which become relevant in each particular case. The benefits which reasonably may be expected to accrue from the proposal must be balanced against its reasonably foreseeable detriments. The decision whether to authorize a proposal, and if so, the conditions under which it will be allowed to occur, are therefore determined by the outcome of this general balancing process. That decision should reflect the national concern for both protection and utilization of important resources. All factors which may be relevant to the proposal must be considered including the cumulative effects thereof: among those are conservation, economics, aesthetics, general environmental concerns, wetlands, historic properties, fish and wildlife values, flood hazards, floodplain values, land use, navigation, shore erosion and accretion, recreation, water supply and conservation, water quality, energy needs, safety, food and fiber production, mineral needs, considerations of property ownership and, in general, the needs and welfare of the people.

The public interest review is thus a balancing test by the USACE of the foreseeable benefits and detriments of proposed projects on an individual and cumulative basis. The following general criteria of the public interest review must be considered in the evaluation of every permit application (see 33 CFR 320.4(a) (2)):

(i) The relative extent of the public and private need for the proposed structure or work

(ii) Where there are unresolved conflicts as to resource use, the practicability of using reasonable alternative locations and methods to accomplish the objective of the proposed structure or work; and
(iii) The extent and permanence of the beneficial and/or detrimental effect(s) that the proposed structure or work is likely to have on the public and private uses to which the area is suited.

The USACE is neither a proponent nor opponent of any permit proposal. The decision to issue or deny a permit is based, in part on the weighing and balancing of the public interest factors. In order to issue a permit, the District Engineer must determine that it would not be contrary to the public interest (33 CFR 320.4(a)). Further, the EPA Guidelines prohibit the issuance of a permit if the discharge is not the least environmentally damaging practicable alternative, or would cause or contribute to significant degradation of waters of the United States (40 CFR 230.10(a)(4).

2.3.1 Environmental Impact Report

The proposed project is subject to review by the Commonwealth of Massachusetts under the Massachusetts Environmental Policy Act (MEPA) because it is being undertaken by a state agency and because it meets or exceeds the review thresholds set forth in the MEPA regulations, including thresholds for a mandatory EIR. The MEPA imposes a requirement on project proponents to understand and fully disclose the potential impacts of a project, both positive and negative; to study feasible alternatives to a project; and to avoid, reduce, or mitigate environmental impacts to the maximum extent feasible. In order to streamline the environmental review process and to facilitate public involvement, MEPA and the USACE are coordinating review of a joint EIS/EIR with the intent to provide the information and analysis required for both federal and state review.

The project is undergoing environmental review pursuant to the following sections of the MEPA regulations at 301 CMR 11.00, which establish the standards for environmental impact review and a basic procedural outline for conducting that review: Section 11.03(a)(1)(5) because it involves construction of a new rail or rapid transit line along a new, unused or abandoned right-of-way; Section 11.03(3)(a)(l)(a) because it will result in alteration of more than one acre of bordering vegetated wetlands (BVW); Section 1 1.02(a)(2) because it involves alteration requiring a variance in accordance with the Wetlands Protection act; Section 11.03(l)(a)(l) and (2) because it may result in alteration of 50 or more acres of land and creation of 10 or more acres of new impervious area; Section 11.03(1 l)(b) because it is located within a designated Area of Critical Environmental Concern (ACEC); Section 1 1.03(b)(3) because it involves conversion of land held for natural resource purposes in accordance with Article 97 of the Amendments to the Constitution of the Commonwealth; Section 11.03(2)(b)(2) because it would result in more than 2 acres of disturbance of designated priority habitat that results in a take of a state-listed species; and Section 1 1.03(10)(b)(l) because it may result in demolition of a part of a state-listed historic structure. The project may also meet or exceed other MEPA review thresholds depending upon its final design. Because the proposed project is being undertaken by a state agency MEPA jurisdiction is broad and extends to all aspects of the project that are likely, directly or indirectly, to cause Damage to the Environment as defined in the MEPA regulations.

Additional state approvals, reviews and permits required for the project include a Water Quality Certification pursuant to Section 401 of the Clean Water Act, a Chapter 91 License and a Variance from the Wetlands Protection Act (WPA) from the Massachusetts Department of Environmental Protection (MassDEP). The project also requires local Orders of Conditions under the WPA (and, on appeal only, Superseding Order(s) from MassDEP). Other permits or approvals required for the project include a Conservation and Management Permit from the Natural Heritage and Endangered Species Program

(NHESP). The project is subject to review by the Massachusetts Historical Commission and the Office of Coastal Zone Management. The project is also subject to the MEPA Greenhouse Gas Emissions Policy and Protocol.

3 ALTERNATIVES

3.1 DEVELOPMENT OF ALTERNATIVES

3.1.1 Introduction

The restoration of passenger rail service to the South Coast region has been extensively studied for almost 20 years. Prior to 1958, the Middleborough, Stoughton and Attleboro rail lines were part of the New York, New Haven and Hartford Railroad system that provided service to Fall River and New Bedford from Boston's South Station, via Canton Junction, along the Stoughton Branch railroad (which included the Whittenton Branch in Raynham and Taunton, running around the northwest edge of the core of the City of Taunton and connecting the Stoughton Line with the Attleboro Secondary). Since discontinuation of this service, commuter rail has only been available to southeastern Massachusetts along the Boston-Providence Northeast Corridor, with stops in Attleboro and South Attleboro, and the Old Colony Middleborough Line, which terminates in Lakeville. Starting in May 2013, MBTA, in cooperation with the Cape Cod Regional Transit Authority, established a seasonal weekends-only service known as the Cape Flyer, extending the Middleborough line from its current terminus in Lakeville, to Hyannis. However, this service is limited to three round-trips per week, all on weekends, and thus serves weekend tourists rather than daily commuters between Boston and the South Coast. Thus, none of these services provide an opportunity for commuters from the Fall River or New Bedford areas to easily or efficiently access rail transportation to Boston.

In 2000, the MBTA completed a Draft EIR that analyzed six alternative routes for providing improved transportation between downtown Boston and the cities of Fall River and New Bedford. The Draft EIR focused on the following alternatives: (1) extending the existing MBTA Stoughton Line, (2) extending the existing MBTA Middleborough Line and (3) providing new service, branching off from the Providence Line near Attleboro. In 2002, a Final EIR was prepared by the MBTA and on August 30, 2002, the Secretary of Environmental Affairs issued a Final Certificate (Executive Office of Environmental Affairs [EEA] File # 10509).

Section 404 of the Clean Water Act Requires a Department of the Army permit for the discharge of dredged or fill material into waters of the United States, including adjacent wetlands. The Department of the Army permit program is administered by the U.S. Army Corps of Engineers (Corps). Since the South Coast Rail Build Alternatives would result in the discharge of fill material into greater than 1 acre of waters of the United States, including wetlands, a Department of the Army Individual Standard Permit is required.[1]

Because the project would require a Clean Water Act permit from the Corps in order to proceed with construction, federal environmental review is required under NEPA. Previous environmental review studies did not take into consideration federal requirements. The Massachusetts Executive Office of Energy and Environmental Affairs also requires review, pursuant to the Massachusetts Environmental Policy Act, due to the lapse of time. To minimize duplication of effort, the Corps and MEPA office agreed that the concurrent NEPA and MEPA reviews should proceed through a combined state and federal environmental review document, in accordance with CEQ regulations at 40 CFR 1506.2. MassDOT (then, the Executive Office of Transportation, or EOT) filed a draft Section 404 Permit Application.

[1] 33 CFR 325.3(b)(1)

Subsequently, the Corps issued a Notice of Intent to prepare an EIS in the Federal Register on October 31, 2008. A public notice was issued by the Corps on November 10, 2008 (NAE 2007-00698).

Both NEPA and MEPA require consideration of a reasonable range of alternatives that could meet the project purpose and need and explanation of why alternatives were eliminated from detailed study (40 C.F.R. § 1502.14(a) and MEPA 301 CMR 11.00(f)). This chapter explains the process that led to the Build Alternatives that are evaluated in this FEIS/FEIR.

In addition, the U.S. Environmental Protection Agency, pursuant to its authority under Section 404(b)(1) of the Clean Water Act, developed *Guidelines for Specification of Disposal Sites for Dredged or Fill Material* (USEPA Section 404(b)(1) Guidelines) and codified same under 40 CFR 230 *et seq*. The USEPA Guidelines stipulate that "...no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences." The USEPA Section 404(b)(1) Guidelines further define, "practicable" as "available and capable of being done after taking into consideration cost, existing technology and logistics in light of overall project purposes." This has generally been interpreted to mean that, in order to comply with the USEPA 404(b)(1) Guidelines, the Corps cannot issue a permit for any project unless it constitutes the least environmentally damaging practicable alternative (LEDPA) for fulfilling the overall project purpose.

The alternatives evaluation described in this chapter was conducted in a manner compatible with the Corps' *Highway Methodology*[2] guidance document to screen alternatives. The Highway Methodology was established to ensure that a transportation agency's preferred alternative under NEPA is consistent with federal wetland regulations, in particular, the Clean Water Act Section 404(b)(1) Guidelines. This chapter also summarizes the characteristics of the alternatives evaluated in this FEIS/FEIR in terms of their anticipated achievement of the overall project purpose, their practicability and their environmental impacts, which together with input from the public and relevant parties will form the basis for the determination of the LEDPA by the Corps.

The alternatives analysis process began with the initial analysis of 65 potential alternatives and subsequent screening, followed by the Corps' Notice Of Intent to prepare an Environmental Impact Statement, the ENF prepared by the applicant, the Certificate on the ENF by the Secretary of the Executive Office Energy and Environmental Affairs (EOEA Secretary) and subsequent studies and analyses during the preparation of the DEIS/DEIR. This process continued through the preparation of the FEIS/FEIR with consideration and analysis of public and agency comments received after publication of the DEIS/DEIR as well as the EOEA Secretary's Certificate on the DEIR.

Throughout this process public, agency and stakeholder input was taken into consideration in the development and evaluation of alternatives, through the federal process, the state environmental review process and public involvement efforts. The Interagency Coordinating Group (ICG)[3] provided an

[2] U.S. Army Corps of Engineers New England Division. 1993. The Highway Methodology Workbook: Integrating Corps Section 404 Permit Requirements with Highway Planning and Engineering and the NEPA EIS Process. Corps Tech. Rpt. NEDEP-360-1-30, 28pp.

[3] The ICG was convened by MassDOT and includes representatives of the United States Army Corps of Engineers; United States Environmental Protection Agency; United States Fish and Wildlife Service; Federal Highway Administration; Federal Transit Administration; National Marine Fisheries Service; Narragansett Indian Tribe; Wampanoag Tribe of Gay Head (Aquinnah); Massachusetts Executive Office of Energy and Environmental Affairs; Massachusetts Environmental Policy Act Office; Massachusetts Bay Transportation Authority; Massachusetts Department of Environmental Protection; Massachusetts Office of Coastal Zone Management; Massachusetts Department of Conservation and Recreation, Areas of Critical Environmental Concern Program; Massachusetts Department of Fish and Game, Natural Heritage and Endangered Species Program; Massachusetts Historical Commission and the Southeastern Regional Planning and Economic Development District.

opportunity for input into the technical analyses for the DEIS/DEIR and was also consulted during the FEIS/FEIR process.

An overview of key steps in the alternatives analysis process is provided below.

3.1.2 Initial (PRE-DEIS/DEIR) Alternatives Analysis Overview

The purpose of the initial alternatives analysis was to identify those alternative concepts that met or exceeded the project evaluation criteria, then to narrow the initial broad range of alternatives to a reasonable number of options that could be carried forward to a more detailed level of analysis in the NEPA/MEPA process.

An initial 65 potential alternatives were identified by reviewing previous studies and soliciting input from the MBTA, the Interagency Coordinating Group, the Commuter Rail Task Force,[4] and interested stakeholders through an extensive civic engagement process conducted by MassDOT. The alternatives are described in detail in the *Analysis of South Coast Rail Alternatives: Phase 1 Report,* Appendix 3.1-A to this FEIS/FEIR. Table 3.1-1, presents the initial list of potential alternatives.[5] Section 3.1.2 of the DEIS/DEIR explained the process of how the alternatives were identified, evaluated, and dismissed or advanced for further evaluation.

These alternatives also included several different components along five main corridors (shown on Figure 3.1-1):

- The Attleboro route (using the active freight rail lines from New Bedford and Fall River to Attleboro, then using the Northeast Corridor from Attleboro to South Station) with a new track bypass or connecting at the existing Attleboro Station.

- The Mansfield route (using the active freight rail lines from New Bedford and Fall River to Taunton, then using the abandoned rail line north to Mansfield Station, then using the active commuter rail line to South Station).

- The Stoughton route (using the active freight rail lines from New Bedford and Fall River to Taunton, then using the inactive rail bed north to Stoughton, then using the active commuter rail tracks to South Station).

- The Middleborough route (using the active freight rail lines from New Bedford and Fall River to the existing Middleborough/Lakeville Station, then using the Old Colony Middleborough Line to South Station)

[4] The Commuter Rail Task Force was formed in 2004 and provides a forum for state officials and local representatives to review and discuss all aspects of the Project and to work toward consensus on strategies and actions to plan ahead for new growth in the region. The Task Force provides advice and assistance to MassDOT and the MBTA in the design of the South Coast Rail Project and in the implementation of the South Coast Rail Economic Development and Land Use Corridor Plan. Its membership includes representatives from the MBTA, regional transit authorities, cities and towns, environmental groups, and business and economic development organizations.

[5] Executive Office of Transportation and Public Works. Analysis of South Coast Rail Alternatives: Phase 1 Report, April 30, 2008.

Table 3.1-1 Initial List of Potential Alternatives

Route	Alt #	Name	Description	How the Alternative was Addressed	Origin
THROUGH ATTLEBORO		***ATTLEBORO SECONDARY***			
	1	Commuter Rail to South Station via Attleboro Bypass	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then west along Attleboro Secondary; new track bypass along National Grid right-of-way to tie into Northeast Corridor north of Attleboro station	Advanced for further consideration	Executive Office of Transportation
	2	Commuter Rail to South Station via Attleboro Station with Reverse Move	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then west along Attleboro Secondary to Northeast Corridor; reverse move at Attleboro Station to merge onto Northeast Corridor	Advanced for further consideration	Executive Office of Transportation
	3	Commuter Rail to South Station via Dartmouth Secondary, New Bedford Secondary, and Attleboro Bypass	Commuter rail along Dartmouth Secondary and New Bedford Mainline north to Cotley Junction, then west along Attleboro Secondary; new track bypass along National Grid right-of-way to tie into Northeast Corridor near Mansfield/Attleboro/Norton town line	Advanced for further consideration	Civic Engagement Process
	4	Bus Rapid Transit to Attleboro Station	Bus Rapid Transit adjacent to New Bedford Main Line track and Fall River Secondary track north to Cotley Junction, then adjacent to Attleboro Secondary west; transfer to Northeast Corridor at Attleboro Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	5	Diesel Multiple Units Commuter Rail to Attleboro Station	Diesel Multiple Units commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then west along Attleboro Secondary; transfer to Attleboro Station	Advanced for further consideration	Civic Engagement Process
	6	Diesel Multiple Units to Attleboro Station with New Bedford to Fall River Connection via Dartmouth Secondary	Diesel Multiple Units commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then west along Attleboro Secondary; transfer to Attleboro Station; additional line along Dartmouth Secondary between New Bedford and Fall River	Advanced for further consideration	Civic Engagement Process
	7	Electrified Commuter Rail to South Station via Attleboro Bypass	Electrified commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then west along Attleboro Secondary; new track bypass along National Grid right-of-way to tie into Northeast Corridor near Mansfield/Attleboro/Norton town line	Advanced for further consideration	Civic Engagement Process
	8	Light Rail to Attleboro	Light rail transit along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then west along Attleboro Secondary; transfer to Commuter Rail at Attleboro Station	Similar operational benefits to Alternative 5 but requires additional infrastructure due to incompatibility of light rail vehicles operating on national rail network	Civic Engagement Process

Route	Alt #	Name	Description	How the Alternative was Addressed	Origin
THROUGH ATTLEBORO	9	Light Rail to Attleboro w/ New Bedford to Fall River connection	Light rail transit along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then west along Attleboro Secondary; transfer to Attleboro Station; additional line along Interstate 195 or Dartmouth Secondary between New Bedford and Fall River	Similar operational benefits to Alternative 6 but requires additional infrastructure due to incompatibility of light rail vehicles operating on national rail network	Civic Engagement Process
	10	Combination Connection to Boston and Providence via Northeast Corridor	Combination of commuter rail on Attleboro Secondary to Boston and commuter bus to connect to Providence, using Interstate 195 corridor	Boston service covered by other alternatives. Providence service does not meet basic project purpose	Civic Engagement Process
	MANSFIELD FORMER RIGHT-OF-WAY				
	11	Commuter Rail to South Station via Mansfield	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, northwest along Attleboro Secondary, then northwest along former right-of-way through Taunton, Norton, and Mansfield to tie into Northeast Corridor near Mansfield Commuter Rail Station	Advanced for further consideration	Corps of Engineers
	12	Bus Rapid Transit to Mansfield Station	Bus Rapid Transit adjacent to New Bedford Main Line track and Fall River Secondary track north to Cotley Junction, then adjacent to Attleboro Secondary track, then northwest along former right-of-way through Taunton, Norton, and Mansfield; transfer to Northeast Corridor at Mansfield Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	13	Diesel Multiple Units Commuter Rail to Mansfield Station	Diesel Multiple Units commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then northwest along Attleboro Secondary, then northwest along former right-of-way through Taunton, Norton, and Mansfield; then transfer to Mansfield Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	14	Diesel Multiple Units to Mansfield Station with New Bedford to Fall River Connection via Dartmouth Secondary	Diesel Multiple Units commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then northwest along Attleboro Secondary to Whittenton Junction, then northwest along former right-of-way through Taunton, Norton, and Mansfield; then transfer to Mansfield Commuter Rail Station; additional line along Dartmouth Secondary between New Bedford and Fall River	Advanced for further consideration	Civic Engagement Process
	15	Electrified Commuter Rail to South Station via Mansfield	Electrified commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then northwest along Attleboro Secondary to Whittenton Junction, then northwest along former right-of-way through Taunton, Norton, and Mansfield to tie into Northeast Corridor near Mansfield Commuter Rail Station	Advanced for further consideration	Civic Engagement Process

Route	Alt #	Name	Description	How the Alternative was Addressed	Origin
THROUGH MIDDLEBOROUGH	16	Light Rail to Mansfield	Light rail transit along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then northwest along Attleboro Secondary to Whittenton Junction, then northwest along former right-of-way through Taunton, Norton, and Mansfield; then transfer to Mansfield Commuter Rail Station	Similar operational benefits to Alternative 13 but requires additional infrastructure due to incompatibility of light rail vehicles operating on national rail network	Civic Engagement Process
	MIDDLEBOROUGH SECONDARY				
	17	Commuter Rail to South Station via Middleborough	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then east along Middleborough Secondary to tie into Middleborough Line	Advanced for further consideration	Executive Office of Transportation
	18	Commuter Rail to South Station via Middleborough, convert Red Line Braintree Branch to Commuter Rail	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then east along Middleborough Secondary to tie into Middleborough Line at new Middleborough/Lakeville Commuter Rail Station relocated north; convert Red Line Braintree Branch to commuter rail	Advanced for further consideration	Civic Engagement Process
	19	Heavy Rail to Middleborough	Extend the Red Line to Middleborough/Lakeville Station via the Middleborough Commuter Rail Line with feeder bus from New Bedford and Fall River	Variation of Alternative 61 (greater infrastructure requirements with no transportation benefits)	Civic Engagement Process
	20	Bus Rapid Transit to Middleborough/Lakeville Station	Bus Rapid Transit adjacent to New Bedford Main Line track and Fall River Secondary track north to Cotley Junction, then east adjacent to Middleborough Secondary; transfer to Middleborough Line at Middleborough/Lakeville Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	21	Diesel Multiple Units Commuter Rail to Middleborough/Lakeville Station	Diesel Multiple Units commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then east along Middleborough Secondary; transfer to Middleborough/Lakeville Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	22	Diesel Multiple Units to Middleborough/Lakeville Station with New Bedford to Fall River Connection via Dartmouth Secondary	Diesel Multiple Units commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then east along Middleborough Secondary; transfer to Middleborough/Lakeville Commuter Rail Station; additional line along Dartmouth Secondary between New Bedford and Fall River	Advanced for further consideration	Civic Engagement Process
	23	Commuter Rail to South Station via Middleborough (via Cotley) -w/ reverse	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then east along Middleborough Secondary to tie into Middleborough Line just north of Middleborough/Lakeville Commuter Rail Station w/	Variation of Alternative 17 (similar infrastructure requirements with no transportation benefits)	Executive Office of Transportation

Route	Alt #	Name	Description	How the Alternative was Addressed	Origin
THROUGH MIDDLEBOROUGH		move	reverse move to serve Middleborough/Lakeville Station		
	24	Light Rail to Middleborough (via Cotley)	Light rail transit along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then east along Middleborough Secondary; transfer to Middleborough/Lakeville Commuter Rail Station	Similar operational benefits to Alternative 21 but requires additional infrastructure due to incompatibility of light rail vehicles operating on national rail network	Civic Engagement Process
	63	Commuter Rail to South Station via Middleborough, also extend Middleborough line to Wareham	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then east along Middleborough Secondary to tie into Middleborough Line; then extend Middleborough Commuter Rail Line to Wareham and/or Buzzards Bay	Advanced for further consideration	Civic Engagement Process
	64	Commuter Rail to South Station via Middleborough without Old Colony Main Line Improvements	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then east along Middleborough Secondary to tie into Middleborough Line; no improvements to Old Colony Main Line	Advanced for further consideration	Interagency Coordinating Group
	MIDDLEBOROUGH FORMER RIGHT-OF-WAY				
	25	Commuter Rail to South Station via Middleborough (via Myricks)	Commuter rail along New Bedford Main Line and Fall River Secondary north to Myricks Junction, then northeast along former right-of-way parallel to Route 79 through Berkley and Lakeville to tie into Middleborough Line at new Middleborough/Lakeville Commuter Rail Station relocated north	Variation of Alternative 17 with minimal transportation improvements and significant environmental impacts (right-of-way takings)	Civic Engagement Process
	26	Commuter Rail to South Station via Middleborough (via Myricks) -w/ reverse move	Commuter rail along New Bedford Main Line and Fall River Secondary north to Myricks Junction, then northeast along former right-of-way parallel to Route 79 through Berkley and Lakeville to tie into Middleborough Line just north of Middleborough/Lakeville Commuter Rail Station w/ reverse move to serve Middleborough/Lakeville Station	Variation of Alternative 17 with minimal transportation improvements and significant environmental impacts (right-of-way takings)	Civic Engagement Process
	27	Light Rail to Middleborough (via Myricks)	Light rail transit along New Bedford Main Line and Fall River Secondary north to Myricks Junction, then northeast along former right-of-way parallel to Route 79 through Berkley and Lakeville; transfer to Middleborough/Lakeville Commuter Rail Station	Similar operational benefits to Alternative 21 but requires additional infrastructure due to incompatibility of light rail vehicles operating on national rail network	Civic Engagement Process

Route	Alt #	Name	Description	How the Alternative was Addressed	Origin
THROUGH STOUGHTON	28	Bus Rapid Transit to Middleborough (via Myricks)	Bus Rapid Transit adjacent to New Bedford Main Line track and Fall River Secondary track north to Myricks Junction, then northeast along former right-of-way parallel to Route 79 through Berkley and Lakeville; transfer to Middleborough Line at Middleborough/Lakeville Commuter Rail Station	Variation of Alternative 20 with minimal transportation improvements and significant environmental impacts (right-of-way takings)	Civic Engagement Process
	29	Diesel Multiple Units Commuter Rail to Middleborough (via Myricks)	Diesel Multiple Units commuter rail along New Bedford Main Line and Fall River Secondary north to Myricks Junction, then northeast along former right-of-way parallel to Route 79 through Berkley and Lakeville; transfer to Middleborough/Lakeville Commuter Rail Station	Variation of Alternative 21 with minimal transportation improvements and significant environmental impacts (right-of-way takings)	Civic Engagement Process
	30	Commuter Rail to South Station via Stoughton	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then north along existing right-of-way through Raynham, Easton, and Stoughton to tie into Stoughton Line at Stoughton Commuter Rail Station	Advanced for further consideration	Executive Office of Transportation
	31	Bus Rapid Transit to Stoughton Station	Bus Rapid Transit adjacent to New Bedford Main Line track and Fall River Secondary track north to Cotley Junction, then north along existing right-of-way through Raynham, Easton, and Stoughton; transfer to Stoughton Line at Stoughton Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	32	Diesel Multiple Units Commuter Rail to Stoughton Station	Diesel Multiple Units commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then north along existing right-of-way through Raynham, Easton, and Stoughton; transfer to Stoughton Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	33	Diesel Multiple Units to Stoughton Station with New Bedford to Fall River Connection via Dartmouth Secondary	Diesel Multiple Units commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then north along existing right-of-way through Raynham, Easton, and Stoughton; transfer to Stoughton Commuter Rail Station; additional line along Dartmouth Secondary between New Bedford and Fall River	Advanced for further consideration	Civic Engagement Process
	34	Electrified Commuter Rail to South Station via Stoughton	Electrified commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then north along existing right-of-way through Raynham, Easton, and Stoughton to tie into Stoughton Line at Stoughton Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
THROUGH STOUGHTON	35	Commuter Rail to South Station via Stoughton (Whittenton Branch)	Variation on Stoughton Alternative using Whittenton Branch and Attleboro Secondary to avoid the Pine Swamp	Variation of Alternative 30 with similar transportation benefits (could be evaluated in Phase 2 as option to Alternative 30	Corps of Engineers

Route	Alt #	Name	Description	How the Alternative was Addressed	Origin
THROUGH ATTLEBOROAND MIDDLEBOROUGH	36	Light Rail to Stoughton	Light rail transit along New Bedford Main Line and Fall River Secondary north to Cotley Junction, then north along existing right-of-way through Raynham, Easton, and Stoughton; transfer to Stoughton Commuter Rail Station	Similar operational benefits to Alternative 32 but requires additional infrastructure due to incompatibility of light rail vehicles operating on national rail network	Civic Engagement Process
	62	Commuter Rail to South Station via Attleboro Bypass and Middleborough Line	Commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction; then one branch west along Attleboro Secondary with new track bypass along National Grid right-of-way to tie into Northeast Corridor north of Attleboro station; second branch along Middleborough Secondary to tie into Middleborough Line just north of Middleborough/Lakeville	Advanced for further consideration	Executive Office of Transportation
	65	Electrified Commuter Rail to South Station via Attleboro and Middleborough	Diesel and electric commuter rail along New Bedford Main Line and Fall River Secondary north to Cotley Junction; then one electric branch west along Attleboro Secondary with new track bypass along National Grid right-of-way to tie into Northeast Corridor north of Attleboro station; one diesel branch along Middleborough Secondary to tie into Middleborough Line just north of Middleborough/Lakeville Station (Middleborough Line not electrified)	Advanced for further consideration	Interagency Coordinating Group
USING HIGHWAY SYSTEM	37	Monorail to South Station via Route 140, Route 24, Route 128, and Southeast Expressway	Monorail along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128/93 right-of-way east and Southeast Expressway right-of-way north to South Station	Advanced for further consideration	Civic Engagement Process
	38	Monorail to Quincy Adams Station via Route 140, Route 24, and Route 128	Monorail along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128/93 right-of-way east; transfer to Quincy Adams Red Line Station	Advanced for further consideration	Civic Engagement Process
	39	Monorail to Route 128 Station via Route 140, Route 24, and Route 128	Monorail along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128 right-of-way west; transfer to Route 128 Commuter Rail Station	Advanced for further consideration	Civic Engagement Process

Route	Alt #	Name	Description	How the Alternative was Addressed	Origin
USING HIGHWAY SYSTEM	40	Commuter Rail to South Station via Route 24 and Route 128 to Northeast Corridor	Commuter rail along New Bedford Main Line and Fall River Secondary north to just south of Cotley Junction, then new track along Route 24 right-of-way north to Randolph and along Route 128/I-93 right-of-way west; tie into Northeast Corridor north of Route 128 Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	41	Light Rail/Heavy Rail to Route 128 Station via Route 140, Route 24, and Route 128	Heavy or light rail transit along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128 right-of-way west; transfer to Route 128 Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	42	Heavy Rail to South Station via Route 140, Route 24, Route 128, and Red Line	Heavy rail transit along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128/93 right-of-way east; tie into Red Line at Quincy Adams Red Line Station	Advanced for further consideration	Civic Engagement Process
	43	Express Bus in Dedicated Lane to Route 128 Station via Route 24 and Route 128	Add HOV lanes on Route 24 from Interstate 495 north to Randolph, then on Route 128 west; transfer to Route 128 Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	44	Express Bus in Dedicated Lane to South Station via Route 24, Route 128, and Southeast	Add HOV lanes on Route 24 from Interstate 495 north to Randolph, then on Route 128/93 east to Southeast Expressway HOV Lane to South Station	Advanced for further consideration	Civic Engagement Process
	45	Enhanced Bus Service on Existing Private Carrier Routes	Increased bus service and increased parking for bus commuters along existing private bus carrier lines from Fall River, New Bedford, and Taunton to South Station	Advanced for further consideration	Executive Office of Transportation
	46	Light Rail to Route 128 Station	Light rail transit along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128 right-of-way west; transfer to Route 128 Commuter Rail Station	Included in Alternative 41	Civic Engagement Process
	47	Light Rail to Quincy Adams Station	Light rail transit along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128/93 right-of-way east; transfer to Quincy Adams Red Line Station	Provides fewer transportation benefits (requires transfer) than Alternative 42 with similar environmental impacts/benefits	Civic Engagement Process
	48	Light Rail to South Station	Light rail transit along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128/93 right-of-way east and Southeast Expressway right-of-way north	Provides similar transportation benefits to HOV lane and similar environmental impacts	Civic Engagement Process

Route	Alt #	Name	Description	How the Alternative was Addressed	Origin
USING HIGHWAY SYSTEM (cont'd)			to South Station	than Alternative 43	
	49	Bus Lane to Route 128	Bus lanes on Route 24 from 495 north to Randolph, then on Route 128 west; transfer to Route 128 Commuter Rail Station	Same transportation and environmental benefits as Alternative 43	Civic Engagement Process
	50	Bus Lane to South Station	Bus lanes on Route 24 from 495 north to Randolph, then on Route 128/93 east to Southeast Expressway HOV Lane to South Station	Same transportation and environmental benefits as Alternative 44	Civic Engagement Process
	51	Combination Connection to Boston and Providence via Route 24	Combination of commuter bus services along I-195 and Routes 24/140 to connect South Coast cities with Providence and Boston	Boston service covered by other alternatives. Providence service does not meet basic project purpose	Civic Engagement Process
	52	Park-and-Ride Improvements	Improve the Park-and-Ride system serving the South Coast	Not a public transit alternative. Does not meet basic project purpose	Civic Engagement Process
	53	Advanced Rapid Transit to Route 128 Station	Advanced rapid transit along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128 right-of-way west; transfer to Route 128 Commuter Rail Station	Provides same transportation and environmental benefits/impacts as Alternative 37 (could be evaluated in Phase 2 as option to Alternative 37)	Civic Engagement Process
	54	Advanced Rapid Transit to Quincy Adams Station	Advanced rapid transit along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128/93 right-of-way east; transfer to Quincy Adams Red Line Station	Provides same transportation and environmental benefits/impacts as Alternative 38 (could be evaluated in Phase 2 as option to Alternative 38)	Civic Engagement Process
	55	Advanced Rapid Transit to South Station	Advanced rapid transit along Routes 24/140 right-of-way from Fall River/New Bedford north to Randolph, then along Route 128/93 right-of-way east and Southeast Expressway right-of-way north to South Station	Provides same transportation and environmental benefits/impacts as Alternative 39 (could be evaluated in Phase 2 as option to Alternative 39)	Civic Engagement Process
Other	56	Commuter Rail to South Station via Providence	Commuter rail along Dartmouth Secondary and old right-of-way through Rhode Island to Providence; tie into Northeast Corridor just north of Providence Commuter Rail Station	Advanced for further consideration	Civic Engagement Process
	57	Enhanced bus on Interstate 195	Public transit service along Interstate 195 between Wareham and Providence	Advanced for further consideration	Civic Engagement Process

Route	Alt #	Name	Description	How the Alternative was Addressed	Origin
Other	58	Commuter Rail to Wareham via Middleborough	Extend the Middleborough Commuter Rail Line to Wareham and/or Buzzards Bay	Advanced for further consideration	Civic Engagement Process
	59	Appoint a czar		Not a public transportation alternative	Civic Engagement Process
	60	Encourage Telecommuting/Video Conferencing		Not a public transportation alternative	Civic Engagement Process
	61	Feeder Bus Network to Middleborough/Lakeville Station	Feeder bus network from New Bedford/Fall River area feeding into existing commuter rail network (may require new station)	Advanced for further consideration	Interagency Coordinating Group

- The Highway route (using Routes 140, 79, 24, 128, and I-93 to the existing Route 128 commuter rail station, the existing Quincy Adams Red Line station, or South Station).

These 65 alternatives were combined into 38 alternatives (Table 3.1-2) by grouping similar alternatives together and dismissing alternatives that were not transportation alternatives. For supporting information on methodology used to develop the ratings shown in Table 3.1-2, refer to Analysis of South Coast Rail Alternatives: Phase 1 Report, Appendix 3.1-A to this FEIS/FEIR.

The alternatives analysis also evaluated using other transportation corridors, including the Dartmouth Secondary (a partially active and partially abandoned freight rail line between New Bedford and Fall River); Interstate 195 between New Bedford and Providence; and active freight rail lines between Lakeville and Wareham.

At the conclusion of the ENF review and public scoping process, the Secretary of the Executive Office of EEA on April 3, 2009 issued a Certificate that specified the analyses, studies, and information to be included in the DEIR and the alternatives to be evaluated:

- No-Build Alternative (Enhanced Bus)
- Attleboro Electric Alternative (Previously referred to as Alternative 1, Option 1B)
- Attleboro Diesel Alternative (Previously referred to as Alternative 1, Option 1A)
- Stoughton Electric Alternative (Previously referred to as Alternative 4, Option 4B)
- Stoughton Diesel Alternative (Previously referred to as Alternative 4, Option 4A)
- Whittenton Electric Alternative (Alternative 4, Option 4D)
- Whittenton Diesel Alternative (Previously referred to as Alternative 4, Option 4C)
- Rapid Bus Alternative (Previously referred to as Alternative 5, Rapid Bus)

Table 3.1-2 Initial Screening List of 38 Alternatives

Route	Alt #	Name	Step 1 Analysis - *Would the Proposed Alternative Achieve the Project Purpose?*	Step 2 Analysis - *Is the Proposed Alternative Practicable?*	Step 3 Analysis - *Compare the Magnitude of Impacts to the natural Environment and Consistency with Smart Growth*

LEGEND
- ● **Highly Favorable**
- ◑ **Favorable**
- ○ **Neutral**
- ⊘ **Unfavorable** (Step 1 alternatives resulting in unfavorable designations were dismissed from further consideration in Phase 1)
- ⊗ **Highly Unfavorable** (Any alternative resulting in highly unfavorable designations were dismissed from further consideration in Phase 1)
- [shaded box] Alternative dismissed from further consideration
- 1 Alternative 17 was removed from further consideration in Step 2, Part 1 but was carried forward to Step 2, Part 2 for comparison purposes at the request of EOT.

The Secretary's certificate and the public and agency comments received in response to the Notice of Intent, ENF, as well as other comments and input from agencies through the Interagency Coordinating Group (ICG) and other channels were taken into consideration by the Corps in its subsequent preparation of the DEIS/DEIR. The Corps and the Executive Office of EEA reached consensus that the above alternatives should be evaluated in the DEIS/DEIR; however, before concluding that they represented a sufficient suite of alternatives to study in detail, the Corps examined an additional permutation. Specifically, during the preparation of the DEIS/DEIR a new alternative that combined the Middleborough Simple Rail Alternative (ENF Alternative 2) with the Rapid Bus Alternative (ENF Alternative 5) was evaluated at the request of EPA. The evaluation (provided in Appendix 3.1--B) indicated that complementing the low ridership of the Middleborough Simple Alternative with the ridership of the Rapid Bus Alternative would result in a combined ridership for the Hybrid Alternative less than that of the Rapid Bus Alternative by itself and just slightly more than the Middleboro Simple Alternative (which was already considered underperforming in terms of ridership). The combination alternative would require much of the infrastructure improvements needed for each individual alternative, resulting in a higher cost of the hybrid alternative than either the Rapid Bus Alternative or the Middleboro Simple Alternative. This would render the cost of the combination alternative not practicable considering costs and logistics in light of overall project purposes (i.e., fewer riders but higher cost of either Rapid Bus or Middleboro Simple alone). This alternative was therefore not advanced for further analysis in the DEIS/DEIR.

Along with the identification of alternative alignments, described in Section 3.1 of the DEIS/DEIR, potential station sites were identified, as described in Section 3.1.4 of the DEIS/DEIR with further detail in the Station Siting Report (FEIS/FEIR Appendix 3.1-C).[6]

3.1.2.1 Station Site Screening

Potential station locations to serve each of the five public transportation alternatives were identified and evaluated with regard to their ability to meet the purpose and need under NEPA, and the overall project purpose under the USEPA Section 404(b)(1) Guidelines pursuant to 40 CFR 230.10(a)(2).

Potential station locations for each of the alternatives were identified early in the process in order to identify potential environmental issues and to be able to calculate the number of riders projected to use each of the alternatives. The number of riders was projected by CTPS using the regional ridership/travel demand computer model commonly used forecast the number of users of a new transit service. The model is based on demographic and geographical factors and service quality variables. Identification of potential station locations also provided insight into the economic development potential of each alternative and opportunities to support economic development in accordance with Smart Growth principles.[7] In addition to the consideration above, a list of guiding principles was used in station screening, consistent with the Commonwealth's Sustainable Development Principles[8,] as described in the Station Siting Report.

Potential station locations for the South Coast Rail alternatives were initially identified by SRPEDD,[9] and screened in an iterative process by the multi-disciplinary project team. SRPEDD staff with input from the public identified a total of 73 rail and bus station locations, some of which overlapped, totaling 55 rail stations and 30 bus stations. The locations identified and remaining in the FEIS/FEIR analysis include

[6] Station Siting Report. EOT's Final Recommendations (October 10, 2008).

[9] SRPEDD is a regional planning agency serving 27 cities and towns in Southeastern Massachusetts.

stations that are located on all potential rail segments, including the Fall River Secondary, New Bedford Main Line, the rail bed that extends south of the Stoughton Station, Whittenton Branch variation on the Stoughton Alternative, and the Attleboro Secondary.

3.1.3 Alternatives Analyzed in the DEIS/DEIR

The following alternatives were analyzed in the DEIS/DEIR. Evaluation of these alternatives was required by the Corps and the Executive Office of EEA, and defined in the MEPA certificate. The alternatives analyzed in the DEIS/DEIR were distinguished between No-Build and Build. Among the Build Alternatives there was a rail mode and a bus mode. Within the rail mode, there were three different corridors (Attleboro, Stoughton and Whittenton) and two different propulsion alternatives: electrically powered and diesel powered, as follows:

- **No-Build (Enhanced Bus) Alternative**
- **Commuter Rail Alternatives**
  - **Attleboro Alternatives**
    - Attleboro Electric
    - Attleboro Diesel
  - **Stoughton Alternatives**
    - Stoughton Electric
    - Stoughton Diesel
  - **Whittenton Alternatives**
    - Whittenton Electric
    - Whittenton Diesel
- **Rapid Bus Alternative**

Figure 3.1-2 provides an overview of the alignments of the alternatives analyzed in the DEIS/DEIR.

The corridor for the Whittenton Alternative is a variant of the Stoughton Alternative. The Whittenton Alternative corridor avoids the Pine Swamp by using the abandoned Whittenton Branch right-of-way. It is identical to the Stoughton Alternative corridor in all other respects.

During the DEIS/DEIR analysis, conceptual operating plans, capital improvement requirements, capital costs, and operating and maintenance costs were developed for each alternative. The DEIS/DEIR alternatives were modeled using the CTPS regional transportation model, providing quantitative results on the performance of each alternative in terms of ridership, highway/vehicular travel, air quality, and environmental justice. Detailed analyses of environmental impacts (to natural resources, air quality, noise and vibration, historic resources, social and economic impacts among others) were conducted. Smart growth strategies were as identified in the South Coast Rail Corridor Plan were evaluated for all Build Alternatives analyzed in the DEIS/DEIR. A detailed description of the alternatives analyzed in the DEIS/DEIR was provided in Section 3.2 of the DEIS/DEIR. Section 3.3 of the DEIS/DEIR summarized the characteristics of each alternative with regard to their achievement of the project purpose and

associated goals and objectives, their practicability and their beneficial effects and environmental impacts.

3.1.4 Comments on the DEIS/DEIR

The DEIS/DEIR was published on February Notice of Availability was published in the Federal Register on March 25, 2011 and made available at various repositories including public libraries, and distributed in hard copy and electronically and on the Corps' web site. The Corps issued a Public Notice on the project on March 23, 2011, coinciding with the MEPA notice in the *Environmental Monitor.* A public comment period ensued following publication of the DEIS/DEIR, inviting written comments on the DEIS/DEIR. Verbal comments were solicited during two public hearings on the DEIS/DEIR. A description of the public and agency involvement following publication of the DEIS/DEIR is provided in Chapter 9, *Public Involvement and Agency Coordination*.

3.1.4.1 Requirements of the Secretary's Certificate

In the Draft Massachusetts Environmental Policy Act Certificate issued on June 2011, the Secretary of Energy and Environmental Affairs stated the following: "I am satisfied that MassDOT has made the case for the Stoughton Route to be brought forward as the preferred alternative in the FEIR…. MassDOT did not identify the preferred mode among the diesel and electric alternatives. However, because the electric option is preferable from an air quality perspective, the Stoughton Electric should be the focus of the FEIR." The Stoughton Alternative is MassDOT's preferred alternative, however MassDOT has not identified a preferred mode (diesel or electric), as discussed in MassDOT's Preface to the FEIS/FEIR.

USACE must comply with NEPA and the Section 404(b)(1) Guidelines, and therefore has different regulatory requirements with respect to alternatives evaluations than the state requirements applicable to MassDOT under MEPA. The FEIS/FEIR analyzes both the Stoughton and Whittenton Alternatives. In addition to electric rail alternatives, the FEIS/FEIR also evaluates the diesel variants to inform the USACE in making its Least Environmentally Damaging Preferred Alternative (LEDPA) determination.

The Secretary's Certificate also requested that the FEIR address the comments listed below. Volume III of this FEIS/FEIR provides detailed responses to all relevant requirements of the Certificate.

- The FEIR should expand on the analysis of the proposed layover facilities with detailed plans for the layover facilities and a comparative analysis of environmental impacts. The FEIR should include a rationale for selection of the preferred layover facilities and for elimination of others from further consideration.

- The FEIR should describe MassDOT's work with the City of New Bedford to develop a feeder bus system and discuss the additional benefits of the system including potential increases in ridership.

- The FEIR should also clarify the enhanced bus measures assumed as part of the No-Build scenario.

- Several stations do not include accommodations for feeder bus. The FEIR should explain this and consider measures to enhance shuttle/feeder bus service to the proposed stations.

- The FEIR should include additional information on station sites, including analysis of decked parking.
- The FEIR should include additional detail on plans to support pedestrian and bicycle access.
- The FEIR should clarify the annual operating schedule for the Battleship Cove Station.
- The FEIR should clarify whether freight currently exists at these [station] sites or not, and if there are any changes to freight routes as a result of the proposed project.
- The FEIR should evaluate the engineering feasibility of constructing the proposed trestle in wetland soils and evaluate the feasibility of constructing a trestle through Pine swamp. The FEIR should also discuss how access will be achieved for any maintenance or emergency situations along the rail right-of-way, including sections of the rail located in the Hockomock and Pine Swamps.

3.1.4.2 Other Comments on the DEIS/DEIR

Other comments on the DEIS/DEIR are summarized below. Volume III of this FEIS/FEIR provides detailed responses to all relevant comments.

- Provide a description of bridge construction techniques and address potential impacts from in-water construction.
- Describe the potential for upgraded at-grade crossing treatments to eliminate the need for whistles and horns within populated areas.
- Provide additional design information regarding the physical improvements, including structures, visual impacts to abutters, and right-of-way impacts associated with the implementation of the electric rail alternatives.
- Provide additional information related to the revised parking layouts at Canton Center Station associated with the Stoughton/Whittenton Alternatives.
- Describe potential construction impacts associated with the construction of new stations and modification of existing stations associated with the Stoughton/Whittenton Alternatives.
- Provide a graphic that shows track assumptions (e.g. single track/dual track and other relevant alignment aspects that affect travel time, including side spurs). Information is needed as to whether or not single tracking in these areas has been fully considered in the calculation of travel time.
- Identify the width of the right-of-way and width of (construction and operation) disturbance of proposed alternatives. Clarify whether all work (construction and maintenance) will fall within the right-of-way and delineate the construction and maintenance zone.
- Include in the capital and operations and maintenance cost of each alternative the costs of mitigation and the financing to construct, operate and maintain each alternative.

- Provide updated or additional information about maintenance and fueling requirements and facilities (fueling stations, inspection tracks and crew quarters, rolling stock maintenance) and how those needs may affect the requirements for a layover facility in Boston.
- Provide updated design plans for station sites with additional information on proposed Transit-oriented Development (TOD).
- Provide a Finance Plan, describe impacts on South Station, describe construction impacts to commuter rail and freight service, and provide a (stations) Parking Plan.
- Describe the feasibility of project phasing, such as sequential completion of lines south of Boston, eventually reaching both Fall River and New Bedford.
- Provide additional information on the number of existing and forecasted freight and passenger trips during the weekday and weekends, with specific attention to the number of existing and future passenger trips at South Station.
- Clarify the specific future improvements and service modifications to the rail corridors that were assumed to be in place for calculating the travel times of rail alternatives (including the No-Build Alternative) by 2030.
- Update the construction schedule for the alternatives and clarify the basis for changes in the construction schedule or lack thereof.
- Provide more specific information regarding freight service under the Stoughton/Whittenton Alternatives, including (if freight service would occur) the hours of operation and potential cargo.
- Provide additional documentation regarding the operational feasibility of the Rapid Bus Alternative, potential necessary improvements and their associated costs, schedule and environmental impacts, both for the Rapid Bus Alternative proposed in the DEIS and any modifications thereto (the additional evaluations of the Rapid Bus Alternative are described below in Section 3.1.5)
- Provide information on the No-Build (Enhanced Bus) Alternative similar to that provided for the Build Alternatives in Section 3.3.
- Provide the mitigation costs associated with the Stoughton, Whittenton and Rapid Bus Alternatives (so they can be incorporated in DEIS Table 3.3-11). Including any additional mitigation costs informed by impact analyses conducted after the DEIS/DEIR was published, including mitigation costs associated with indirect impacts.
- Clarify changes, if any, in cost per rider estimates for the Rapid Bus Alternative and other alternatives, as applicable, in the DEIS relative to earlier (pre-DEIS) estimates.
- Provide a discussion of areas like Route 24 where the bus will operate in its own designated lane and whether the bus route can be designed to operate safely at higher speeds to reduce overall travel time.

- Identify measures to reduce congestion that the bus service will face as it enters the mixed traffic portion of its route along the Southeast Expressway.
- Confirm that rapid bus vehicles would incorporate passenger comfort and convenience features (such as Wi-Fi).
- Conduct further evaluation of issues associated with the Rapid Bus Alternative to determine the extent to which there could be improvements in that alternative's overall performance.
- Clarify whether any one change or combination of changes, to the Rapid Bus Alternative would result in a meaningful change in ridership.
- Provide information on the feasibility and ridership effects of a connection between the proposed Rapid Bus service and the MBTA's Orange Line.
- Provide information on the feasibility and ridership effects of additional stations in areas of proposed growth.
- Clarify the specific (traffic/congestion/roadway configuration) data and how this caused an increase in reported Rapid Bus travel time compared to previous analyses.
- Update on-time arrival data of existing services to reflect more current data and clarify how on-time performance data relates to the total estimated travel time of proposed alternatives and their on-time performance.
- Clarify the definitions of the South Coast Region for different purposes, including the definition of the South Coast Region that was used to calculate the (8,000) daily work trips to the Boston area and how the ridership demand for a region relates to the ridership demand for a specific service/alternative.

3.1.5 Alternatives Eliminated following the DEIS/DEIR

This section briefly describes the alternatives eliminated from further analysis following the DEIS/DEIR and the rationale for not advancing these alternatives to this FEIS/FEIR.

3.1.5.1 Attleboro Alternatives

The Attleboro Alternative would provide commuter rail service to South Station using the Northeast Corridor, proposed Attleboro Bypass, Attleboro Secondary, New Bedford Main Line, and Fall River Secondary. Both electric (Attleboro Electric) and diesel (Attleboro Diesel) commuter rail options were evaluated for this alternative. The New Bedford route would be 60.4 miles long and the Fall River route would be 57.9 miles long.

The Attleboro Alternative (electric and diesel) would include eight new commuter rail stations (Barrowsville, Downtown Taunton, Taunton Depot, King's Highway, Whale's Tooth, Freetown, Fall River Depot, and Battleship Cove) and major reconstruction at three existing commuter rail stations (Canton Junction, Sharon, Mansfield) as well as minor work at the existing commuter rail station at Route 128.

The Attleboro Alternatives would require improvements to track infrastructure along the Northeast Corridor (construction of a third track between the proposed Attleboro Bypass and the Readville

Interlocking in Boston, a distance of 18.7 miles); the Attleboro Bypass (a new two-track railroad on a new right-of-way between the Northeast Corridor and the Attleboro Secondary, a distance of 2.8 miles); and the Attleboro Secondary (reconstruction of existing tracks from the Attleboro Bypass to Weir Junction, as a single track with one siding, a distance of 9.7 miles). This alternative also requires reconstructing track on the Southern Triangle, which is common to all rail alternatives, including the New Bedford Main Line (reconstruct existing tracks from Weir Junction to New Bedford, as two to three tracks from Weir Junction to Myricks Junction and single track with three sidings from Myricks Junction to New Bedford, a distance of 18.9 miles); and the Fall River Secondary (reconstruct existing tracks from Myricks Junction to Fall River, as single track with three sidings, a distance of 11.8 mile).

Based on RAILSIM capacity simulations, the Attleboro Alternatives would operate with very poor on-time performance (especially in the evening peak period) (See Appendix 3.1-D). The analysis indicated that the Attleboro Alternatives would be operationally infeasible as they would not meet the MBTA on-time standard in the morning peak and would experience even worse on time performance during the evening peak commute. The Attleboro Alternatives would also contribute to a cascading negative impact on the on-time performance of the entire southerly commuter rail system, including Worcester, Franklin, Needham, and Providence commuter rail lines.

In order to address the operational infeasibility of the Attleboro Alternative, capacity on the Northeast Corridor (NEC) would have to be increased through construction of a fourth track along the NEC between Forest Hills Station and Back Bay Station. An analysis was conducted in the DEIS/DEIR of the construction costs and schedule implications as well as key property and other impacts associated with the construction of a fourth track.

The analysis in the DEIS/DEIR (Section 1.4.6.2) indicated that the potential impacts, construction costs and construction schedule and other aspects of the fourth track along the NEC would render implementation of this infrastructure requirement not practicable considering costs, existing technology and logistics in light of overall project purposes. In a previous study, the Federal Railroad Administration (FRA; a cooperating federal agency) also explored the option to expand capacity of the NEC north of Canton Junction Station. However, due to substantial constraints, it was proposed that such capacity expansion end at Forest Hills in Jamaica Plain. In reviewing the RAILSIM capacity simulations conducted for the Attleboro Alternative, the FRA indicated to the Corps during the preparation of the DEIS/DEIR that it considered the Attleboro Alternatives infeasible and appropriate to eliminate from further environmental review/ consideration.[10]

3.1.5.2 Rapid Bus Alternative

As proposed at the time of the DEIS/DEIR, the Rapid Bus Alternative would provide commuter bus service to South Station via I-93, Route 140 and Route 24. North of I-495, buses would use a combination of new zipper bus lanes, new reversible bus lanes, two-way bus lanes, existing zipper HOV lanes, and existing HOV lanes, along with a short section in mixed traffic. South of the I-495 interchange in Raynham, buses would travel in the general purpose lanes with mixed traffic. The New Bedford route would be 56.4 miles long and the Fall River route would be 51.5 miles long.

This alternative requires improvements to highway infrastructure along Route 24 (construct third lane from Route 140 to I-495, a distance of 5.8 miles; widen Route 24 to accommodate movable barriers; construct zipper bus lane from I-495 to Harrison Boulevard, a distance of 15.4 miles); and Route 128/I-

[10] Email correspondence from FRA to Army Corps. March 3, 2010.

93 (construct reversible bus lane from Harrison Boulevard on Route 24 to Logan Express Lot, a distance of 4.2 miles; and construct two-lane bus roadway from Logan Express Lot to existing HOV zipper lane on the Southeast Expressway, a distance of 1.6 miles). Infrastructure improvements also include constructing, reconstructing, or widening 20 bridges and reconstructing 11 highway interchanges.

This alternative would include six new rapid bus stations (Downtown Taunton, Galleria Station, King's Highway, Whale's Tooth, Freetown and Fall River Depot).

After publication of the DEIS/DEIR several comments were received on the Rapid Bus Alternative described and analyzed in the DEIS/DEIR, prompting additional analysis of this alternative. The comments received on the DEIS/DEIR Rapid Bus Alternative can be summarized as follows:

Performance: Travel speed of the DEIS/DEIR Rapid Bus Alternative was identified as too slow. The slow travel speed did not make the alternative competitive with rail. Further analysis of speed improvements was requested, including additional opportunities for the Rapid Bus Alternative to operate in its own designated lane or at higher speeds. Overall reductions in travel time would be the objective of these modifications.

Congestion: It was noted that the Rapid Bus Alternative was subjected to congestion "hot spots," which would affect its projected travel time and reliability. It was suggested that the Rapid Bus Alternative include additional measures to address congestion.

Ridership: Ridership on the Rapid Bus Alternative was noted as being lower than the commuter rail alternatives. The May 2010 memo from Central Transportation Planning Staff (CTPS) accompanying the projections indicated the following major factors contributing to lower performance of the Rapid Bus Alternative than the commuter rail alternatives:

1. Run times of the Rapid Bus Alternative are longer to South Station than commuter rail alternatives;
2. The commuter rail alternatives serve several more stations than the Rapid Bus Alternative ;
3. Lack of connectivity of the Rapid Bus Alternative with the Orange Line;
4. Transfer times between the Rapid Bus Alternative and the rapid transit lines are a little longer than with the commuter lines;
5. The Rapid Bus Alternative would include fewer new stations in areas of projected growth compared to the commuter rail alternatives
6. The Rapid Bus Alternative's lack of intra-regional connectivity/no intermediate stations, compared to the commuter rail alternatives.

As described in the DEIS/DEIR the Rapid Bus Alternative had by far the lowest ridership among the alternatives, while having the greatest impact on wetlands (a loss of 21.5 acres of wetlands, of which 4.0 acres were in state designated Areas of Critical Environmental Concern (ACEC); a loss of 16.3 acres of priority habitat for three state-listed species; and a loss of 4.5 acres of Article 97 public open space), coupled with the lowest air quality benefits (a 9.3 kg/day reduction in volatile organic compounds

[VOCs] and a 6,588 tons/year reduction in carbon dioxide [CO_2]), resulting in a greater overall environmental impact.

In response to the comments received on the DEIS/DEIR the Rapid Bus Alternative was re-evaluated and modified as described below.

3.1.5.3 Modified Rapid Bus Alternative

To address the concerns summarized above and make the Rapid Bus Alternative more competitive with rail and increase its ridership several operational and infrastructure improvements to the Rapid Bus Alternative were identified. These improvements were designed to reduce travel times, increase reliability, and connectivity of the Rapid Bus Alternative by:

- Eliminating bottlenecks associated with the Zipper Lane;
- Improving connection to Back Bay employment area by directly routing some service; and
- Providing additional Rapid Bus Alternative stations in the vicinity of stations proposed for the commuter rail alternative, specifically the Raynham and Easton areas.

Multiple alternatives were developed and evaluated based on the criteria established in the DEIS/DEIR. The changes that were selected and became part of the Modified Rapid Bus Alternative are described in detail in Appendix 3.1-E: *Modified Rapid Bus Alternative Technical Memorandum*.

In developing the Modified Rapid Bus Alternative several major constraints and concerns were identified:

- A fully exclusive bus lane (to reduce travel time) could not be feasibly constructed all the way into Boston;
- Because the Modified Rapid Bus Alternative requires using a section of the existing highway system that is already subject to heavy congestion and is vulnerable to significant delays, the reliability of the Modified Rapid Bus Alternative would be severely impacted, which would negatively affect ridership;
- While capital costs would be lower, the operating and maintenance costs of the Modified Rapid Bus Alternative would be more than double those of the Stoughton Electric Alternative, while the Modified Rapid Bus Alternative would have substantially lower ridership than the Stoughton Electric Alternative. This would result in a cost per boarding of the Modified Rapid Bus Alternative almost twice that of the Stoughton Electric Alternative; and
- The Modified Rapid Bus Alternative would have twice as much wetland impact (in area) as the DEIS/DEIR Stoughton Electric Alternative and approximately 30 percent less air quality benefit based on a reduction of annual CO_2 emissions.

In sum, the Modified Rapid Bus Alternative would still have substantially lower ridership, much higher cost and greater adverse environmental impact compared to the commuter rail alternatives.

The Federal Highway Administration (FHWA) provided its review of the DEIS/DEIR Rapid Bus Alternative and subsequent related information (including the Modified Rapid Bus Alternative).[11] The role of the FHWA as a cooperating agency on the EIS for the South Coast Rail project is to provide special expertise and technical assistance with respect to issues concerning the transportation system.

The FHWA, if it were expected to have an approval action on the selected alternative, would need to comply with NEPA for its action, and as a cooperating agency in the current NEPA review FHWA could adopt the environmental document that is prepared for the project in compliance with NEPA. Its review of the Modified Rapid Bus Alternative therefore examined the alternative from the perspective of both responsibilities as cooperating agency for the Corps NEPA review and as a potential decision-maker for such an alternative. The Rapid Bus Alternative would use a segment of the National Highway System, which includes the Interstate System in which the FHWA also has a special interest: FHWA's Policy on Access to the Interstate System reflects Congressional intent and direction provided in transportation legislation, reiterates FHWA's responsibility to preserve and enhance the Interstate System, and meets the needs of the 21st Century by assuring that the Interstate System provides the highest level of service in terms of safety and mobility.

The FHWA commented that "Based on the information provided in the DEIS and related materials, it is our opinion that the analysis of the Rapid Bus Alternative accurately presents the impacts to the transportation corridor and the region. Furthermore, FHWA believes that the impacts to the roadway network, in particular those which degrade service on the Interstate System associated with the Rapid Bus Alternative and its various modifications are unacceptable, and thus the alternative is not a viable option"

In sum, the substantial analysis conducted for the Rapid Bus Alternative during the DEIS/DEIR and subsequent consideration of optimized Modified Rapid Bus Alternatives (see Appendix 3.1-E), including its multiple design variations, indicates very low ridership, fewer regional mobility benefits (interregional links), greater impact on the environment and on the transportation system than the rail alternatives and high cost of the (Modified) Rapid Bus Alternative and its variants. The Corps has thoroughly considered this data and the determination by the FHWA (in its capacity as a Cooperating Agency with technical expertise on this alternative) of this alternative as non-viable. The Corps concludes that, at best, the Modified Rapid Bus Alternative (1) meets the overall project purpose only marginally by generating approximately 1/3 fewer riders than MassDOT's preferred alternative, (2) is unreasonably costly to construct and maintain (more than double the annual operating and maintenance cost of the Stoughton Electric Alternative), and (3) is logistically infeasible to construct in a manner that would not be highly likely to eventually degrade the already stressed Interstate Highway transportation system. Accordingly, the Corps has determined that the Modified Rapid Bus Alternative is not practicable, after taking into consideration cost, existing technology and logistics in light of overall project purposes (40 CFR 230.10(a)(2)), and therefore, the alternative was eliminated from further consideration in the FEIS/FEIR.

3.2 DESCRIPTION OF ALTERNATIVES EVALUATED IN THE FEIS/FEIR

This section provides a description of the alternatives evaluated in the FEIS/FEIR: the No-Build (Enhanced Bus) Alternative (which does not meet the purpose and need for the project, but serves as a

[11] Letter from FHWA to USACE re: South Coast Rail Project. January 17, 2013.

baseline for the analysis of the Build Alternatives), the Stoughton Alternative (electric and diesel variants) and the Whittenton Alternative (electric and diesel variants).

Consistent with the Secretary's Certificate on the DEIR, MassDOT advanced the design of the Stoughton Electric Alternative. This included a more accurate estimate of project impacts, constructability, mitigation measures, and costs. The operating plan has also been refined to optimize travel times and reduce conflicts with freight service. Specific alterations to the DEIS/DEIR alternative design are identified in each specific section.

Subsequent to the publication of the DEIS/DEIR, the Corps requested MassDOT to provide additional data such that the Corps could further evaluate alternatives in the FEIS/FEIR. The Corps did not disagree with any of the items contained in the Secretary's certificate on the FEIR; however the Corps noted that additional data was necessary to ensure that options other than the Stoughton Electric Alternative were addressed. Accordingly, the Corps required additional information concerning the Rapid Bus (discussed above) and Whittenton Alternatives, and also required additional data concerning cultural resource impacts to ensure that (1) all practicable alternatives would be fully analyzed in the FEIS/FEIR, and (2) due consideration would be given to the potential effects of the alternatives on cultural resources as well as other environmental considerations.

This section includes information on the engineering design of the track infrastructure, bridges, stations, and layover facilities associated with the Stoughton and Whittenton Alternatives. It also includes an updated operations analysis in Section 3.2.8.2. Section 3.2.19 provides information on construction of each of the project elements. Additional information on the feeder bus system, grade crossings, bridges, and the layover facility site selection is presented in the appendices 3.2-A and 3.2-E to this FEIS/FEIR.

3.2.1 Overview of Build Alternatives Corridors

The following sections describe the rail corridors within which the proposed Build Alternatives would be constructed. Aspects discussed include corridor location, current conditions, constraints, issues, and ownership.

This section describes those transportation corridors associated with the Stoughton, and Whittenton (electric and diesel) rail options. The organization of the description of these corridors forms the basis for the characterization of the affected environment and environmental consequences of the rail alternatives in Chapter 4.

3.2.1.1 The "Southern Triangle"

This section, common to all rail alternatives, provides an overview of two components of the transportation system south of Weir Junction, referred to as the "Southern Triangle." These components include the New Bedford Main Line and the Fall River Secondary.

New Bedford Main Line Rail Segment

The New Bedford Main Line is an active rail line running from the Attleboro Secondary at Weir Junction in Taunton to the waterfront piers in New Bedford. The line connects with the Middleborough Secondary at Cotley Junction and the Fall River Secondary at Myricks Junction. The line is in service for freight only at the present time. The line is mostly single track (but was constructed to carry two tracks), with a two-track section north of Cotley Junction. The line was acquired from CSX by MassDOT.

The line passes through some environmentally sensitive areas, including Assonet Cedar Swamp in Berkley and Lakeville and is adjacent to Acushnet Cedar Swamp State Reservation in New Bedford. Other constraints include dense development along the line in New Bedford.

Fall River Secondary Rail Segment

The Fall River Secondary is an active rail line running between the New Bedford Main Line at Myricks Junction in Berkley and the waterfront in Fall River. The line is in service for freight only at the present time. The line is all single-track, and was acquired by MassDOT from CSX.

The line passes through some environmentally sensitive areas, including Assonet Cedar Swamp in Berkley. Other constraints include dense development along the line in Fall River, and large slopes above and below the line in Fall River along the Taunton River.

3.2.1.2 Northeast Corridor Rail Segment

The Northeast Corridor is an active rail line running between New York City and South Station in Boston. The portion of interest for this project runs from Attleboro to Boston. The corridor experiences heavy use, including Amtrak Regional and Acela service, MBTA commuter rail service, and freight rail service. The MBTA Providence Line uses the entire length of this portion of the corridor; the Stoughton Line, Franklin Line, and Needham Lines join farther north at Canton Junction, Readville, and Forest Hills, respectively.

The corridor has at least two tracks on this section, with three tracks from Readville to Boston. There are also two station siding tracks at Attleboro Station. The corridor is electrified, meaning that both diesel and electric trains can operate, and is designed and signaled for high-speed rail operations. The corridor is owned by the MBTA. Train operations are controlled by Amtrak. In general, the majority of the Northeast Corridor north of Canton Junction is highly developed and lacks environmentally sensitive areas.

3.2.1.3 Attleboro Secondary Rail Segment

The Attleboro Secondary is an active rail line running from the Northeast Corridor in Attleboro to the Stoughton Line and New Bedford Main Line at Weir Junction in Taunton. The line is in service for freight only at the present time. The line is mostly single track, with a two-track section just east of the Northeast Corridor in Attleboro. The line is currently owned by MassDOT and operated by CSX.

The line runs through some environmentally sensitive areas, including Chartley Pond and the Three Mile River ACEC. It also has many grade crossings in downtown Taunton, because it runs directly through the densely developed core of the city.

3.2.1.4 Stoughton Alternatives Corridor

This section provides an overview of the Stoughton Main Line, the main component of the transportation corridor for the Stoughton Alternatives under consideration. Alternatives through Stoughton would also use the Northeast Corridor north of Canton Junction (for a description of the Northeast Corridor, see Section 3.2.1.2).

The Stoughton Main Line is a rail line running from the Northeast Corridor at Canton Junction to the Attleboro Secondary and New Bedford Main Line at Weir Junction in Taunton. The line is active between Canton Junction and Stoughton Station serving commuter rail on the MBTA Stoughton Line and freight

rail to customers in Canton and Stoughton. A short piece of the line north of Weir Junction is active, serving freight only. Service along the remainder of the line, from Stoughton Station to Raynham Junction was discontinued in 1958, and the segment between Raynham Junction and Taunton, has been abandoned since approximately 1916. Tracks have been removed between Longmeadow Road, Taunton and Short Street, Easton.

The active sections of the corridor are single-track, except at the approach to Canton Junction, where there are two tracks. The corridor is owned by the MBTA, north of Britton Street in Raynham. Parts of the right-of-way north of Longmeadow Road in Taunton were sold and are today in various public/private ownership. The active rail segment north of Weir Junction is owned by MassDOT and operated by the MassCoastal Railroad.

The corridor runs through some environmentally sensitive areas, including Pine Swamp in Raynham and the Hockomock Swamp ACEC in Easton. Hockomock Swamp is one of the most important wetlands in the state for rare species habitat and protects regional water quality.

3.2.1.5 Whittenton Alternatives Corridor

This section provides an overview of the main component of the transportation corridor for the Whittenton Alternatives under consideration. Like the Stoughton Alternatives, the Whittenton Alternatives would use the Northeast Corridor north of Canton Junction to the Stoughton Main Line to the Whittenton Branch. The Whittenton Branch is an abandoned rail line in Raynham and Taunton, running around the northwest edge of the core of the City of Taunton and connecting the Stoughton Line with the Attleboro Secondary.

The corridor runs through the Hockomock Swamp ACEC in Easton but would avoid impacts to Pine Swamp in Raynham. The Whittenton Branch is currently owned by the MBTA.

The Whittenton Alternative represents the corridor that was last used to carry passenger trains between South Station and New Bedford. Use of the Whittenton line by rail ceased as passenger service was discontinued in 1958.

3.2.2 Description of Build Alternative Modes

The following sections describe the modes used by the FEIS/FEIR alternatives and the operating assumptions used to evaluate each mode.

3.2.2.1 Diesel Commuter Rail

Diesel commuter rail refers to a fixed-guideway system with steel wheels operating on steel rails, with one or two locomotives pulling a number of passenger coaches; on the MBTA system, train sets are generally six to nine coaches. Coaches would be bi-level, to increase capacity. Figures 3.2-1 and 3.2-2 depict a typical cross-section of a conventional commuter rail.

Diesel commuter rail maximum speed was assumed to be 79 mph, the maximum currently operated on the MBTA system. For

purposes of comparing alternatives, headways[12] for commuter rail alternatives were set at 30 minutes on the branches (Fall River Secondary and New Bedford Mainline) and 18 minutes on the trunk, during the peak period in the peak direction. Scheduled travel times on existing services were not altered.

3.2.2.2 Electric Commuter Rail

Electrified commuter rail refers to a fixed-guideway system with steel wheels operating on steel rails, with one or two locomotives pulling a number of passenger coaches. For consistency with the MBTA system, train sets are assumed to be six to nine coaches. Coaches would be bi-level to increase capacity. Electrified commuter rail locomotives are powered by an overhead electrical contact system. Figures 3.2-3 through 3.2-5 depict a typical cross-section of an electrified commuter rail.

For electric commuter rail, the maximum speed was assumed to be 100 mph, the maximum speed that can be operated without incurring significant signal costs because of the need to signal civil restrictions. For purposes of comparing alternatives, headways for electric commuter rail alternatives were set at 30 minutes on the branches and 18 minutes on the trunk, during the peak period in the peak direction.

3.2.3 No-Build Alternative – Enhanced Bus

The No-Build Alternative is described here in further detail to respond to the Secretary's Certificate. Under this alternative, no new rail or bus service would be provided to Southeastern Massachusetts; however, existing bus routes would be enhanced. The No-Build Alternative would improve transit service to Boston from New Bedford, Fall River, and Taunton by adding more buses with smaller capital investments than are proposed in the Build (i.e., Stoughton and Whittenton) Alternatives.

The South Coast Rail study area includes commuter rail and bus service and associated infrastructure such as commuter rail stations and park-and-ride lots. Also included in the No-Build Alternative is the reconstruction of existing railroad bridges, already underway in New Bedford. This reconstruction addresses existing maintenance needs to ensure safe operation of active freight trains currently using the New Bedford Main Line. The analysis of the No-Build Alternative also assumes the expansion of South Station and the construction of a new mid-day facility in Boston, as currently proposed by MassDOT to better meet existing passenger rail needs (see below). These improvements would be implemented irrespective of the South Coast Rail alternatives.

3.2.3.1 No-Build Commuter Rail Service

No commuter rail service is offered within the South Coast area. Although commuter rail service is offered in nearby southeastern Massachusetts communities by the MBTA, this service is difficult for most residents to access and is approaching or over capacity under existing conditions, as shown in Table 3.2-1.

[12] The interval of time between two trains boarded by the same unit at the same point. Dictionary of Military and Associated Terms. US Department of Defense 2005.

The Attleboro/Providence Line has stations in Providence, South Attleboro, Attleboro, Mansfield, and Sharon. The Stoughton Line has stations in Stoughton, Canton Center and Canton Junction and the Middleborough Line has stations in Brockton, Bridgewater, and Middleborough/Lakeville. Several communities located on the fringes of the South Coast area, including Easton, Raynham, Norton, and Lakeville, are near existing commuter rail stations.

Communities in the heart of the South Coast area, however, are outside a 6-mile access radius of these stations, and some are more than 20 miles from the nearest commuter rail station.[13] Commuter rail is currently not a reasonable alternative for most South Coast area residents traveling to Boston, especially from the communities of Taunton, Berkley, Freetown, Fall River, New Bedford, Dartmouth, and Westport due to the distance from the nearest station.

Table 3.2-1 Ridership on Providence, Stoughton and Middleborough Rail Lines

Line	AM Peak Passengers	AM Peak Seating Capacity	AM Peak Utilization*
Providence	11,017	8,532	129%
Stoughton	2,771	3,558	78%
Middleborough	3,743	3,696	101%

Source MBCR Ride Check December 2006, MBTA South Side Equipment Schedule
* Assumes all passengers continue to South Station, Stoughton, Providence/Stoughton and Middleborough/Lakeville Lines.

While residents from Lakeville are able to use commuter rail to commute to Boston, system capacity is limited. Commuter rail station parking lots in Attleboro, Mansfield, Stoughton, and on the Middleborough Line are either currently unable or will soon not be able to handle any more growth, and communities are reluctant to increase parking lot capacity. In addition, some peak hour trains experience heavy passenger loads. Therefore, the existing commuter rail service, although within reach of some communities in the South Coast area, is not sufficient to handle the current demand and anticipated growth in ridership.

3.2.3.2 No-Build Commuter Bus Service

Existing commuter bus service to Boston from New Bedford, Fall River, and Taunton is currently provided by three commuter bus carriers: DATTCO provides Boston-New Bedford service; Peter Pan provides Boston- Fall River bus service; and Bloom provides Boston-Taunton service. Figure 3.2-6 shows these routes.

These bus companies offer a fare structure that is competitive to commuter rail service. The three commuter bus routes travel through the downtown core of New Bedford, Taunton, and Fall River. The routes all board passengers in the downtown before traveling to other locations to pickup/drop-off passengers at external bus stops/park-and-ride lots and intermediate flag stops. The Fall River commuter bus runs express to Boston with no intermediate stops.

In addition to the private commuter bus service to Boston, two regional transit authorities (RTAs) provide transit service in the study corridor: SRTA operates in New Bedford and Fall River sub-region, and GATRA operates in the Taunton/Attleboro area sub-region. Each RTA shares terminal facilities with commuter bus companies. These authorities share infrastructure and terminals with the commuter bus

[13] According to CTPS, most commuter rail riders live within 6- to 8-miles of a commuter rail station. This distance is generally used for estimating ridership.

carriers and provide passengers an intermodal link from other points within the local communities to the Boston commuter bus service.

South Coast Regional Bus Service

SRTA serves the communities of New Bedford, Fall River, and Somerset with fixed route and demand responsive services. SRTA operates 10 routes in the New Bedford area, 11 routes in the Fall River area, and one route between New Bedford and Fall River. SRTA has downtown terminal stations, both in Fall River and New Bedford, where the commuters could transfer directly to the commuter buses to Boston. New Bedford weekday service generally begins between 5:30 and 6:30 AM and ends roughly between 6:30 and 7:30 PM. Fall River weekday service begins between 6:00 and 7:00 AM and ends between 5:30 and 6:30 PM. SRTA operates on Saturday from 7:00 AM to 6:00 PM in New Bedford and from 6:30 AM to 7:00 PM in Fall River. There is no Sunday bus service in either New Bedford or Fall River.

GATRA primarily serves the communities of Attleboro and Taunton with fixed route bus service and demand responsive service. GATRA operates 14 fixed routes and two intercity routes. GATRA has a terminal station on Oak Street in Taunton where commuters could transfer directly to commuter buses to Boston. The various GATRA bus routes operate Monday through Friday beginning between 5:30 and 6:30 AM and ending between 6:00 and 7:00 PM. GATRA Saturday bus service begins at 9:00 AM and ends at 5:00 PM. There is no Sunday bus service.

New Bedford to Boston Bus Service

New Bedford to Boston commute originates in Fairhaven at the bus terminal and maintenance facility at 72 Sycamore Street. This service has three intermediate stops along the route to Boston: SRTA Terminal in downtown New Bedford, Mt. Pleasant Street park-and-ride in New Bedford, and Silver City Galleria park-and-ride in Taunton. The SRTA terminal in downtown New Bedford is the main station stop that provides service to the SRTA fixed route bus service and provides covered terminal area for loading and unloading passengers for SRTA and DATTCO buses. The terminal is located in Downtown New Bedford at the corner of Elm Street and Pleasant Street. There is covered parking above the terminal for approximately 80 cars, but is allowed by permit only and is at capacity. These spaces are primarily used by employees who work in the downtown area.[14] Commuters to Boston use the Elm Street Garage nearby or travel north to the Mt. Pleasant Street park-and-ride for all-day parking. The commuter bus terminates and originates service from South Station Bus Terminal in Boston. Figure 3.2-6 depicts the New Bedford bus route to Boston.

There is a small terminal area at the Fairhaven location that DATTCO uses to provide bus storage, maintenance, office space, and a waiting area for up to two buses. There are 28 striped parking spaces in the surface lot adjacent to the bus waiting area for commuters. Additional passengers are also likely to be dropped-off/picked-up and walk or bike to the terminal from the local neighborhoods.

SRTA's FY 2009-2012 Transportation Improvement Program (TIP) includes funds for renovations to the terminals and garages.

New Bedford to Boston Bus Operations—The weekday schedule for the bus from New Bedford to Boston includes 11 trips inbound and 11 trips outbound. The weekday inbound morning commute operates five trips on half-hour headways from 4:50 AM to 6:50 AM and then 120-minute headways for the remaining inbound trips. The weekday outbound evening commute operates five trips on various

[14] Based on discussion with SRTA administration.

headways beginning with a 45-minute headway at 4:00 PM, and then half-hour headways, followed by one 60-minute headway with the last peak trip leaving at 6:45 PM. One final outbound trip departs at 9:00 PM. Weekend service includes four trips inbound and four trips outbound stopping at the same stops served during weekday service. The inbound service begins at 6:50 AM and operates on four-hour headways until 6:50 PM. The outbound service begins at 9:00 AM and also operates on four hour headways until 9:00 PM.

Based on the schedule, travel times inbound range from 120 minutes in the peak period to 95 minutes in off peak periods. Travel times outbound range from 100 minutes during peak period to 85 minutes during the off peak period.

Fall River to Boston Bus Service

The Fall River commuter bus service to Boston is an express service from downtown Fall River at the corner of Third Street and Borden Street to South Station Bus Terminal in Boston. The service originates in Newport, Rhode Island and then travels to the temporary trailer bus terminal located on Borden Street in Fall River. This temporary terminal serves both SRTA and Peter Pan buses and provides for ticketing purchases within the trailer bus terminal building. A new bus terminal is planned near or at the location of the current terminal. Figure 3.2-6 depicts the Fall River bus route to Boston.

The SRTA FY 2009 TIP includes plans to replace the SRTA bus terminal in Fall River (razed for the construction of the Fall River Courthouse). SRTA also plans continual renovations to the terminals and garages listed in the fiscal year 2009-2012 TIP.

Fall River to Boston Bus Operations—The weekday schedule for the bus from Fall River to Boston is more limited than that of New Bedford, offering six trips inbound and six trips outbound. The weekday inbound morning commute operates three trips with the first departing at 6:00 AM and then the next on a 40-minute headway and the next on a 120-minute headway. The weekday outbound evening commute operates three trips on 60-minute headways beginning at 4:30 PM. Weekend service is the same schedule as weekday except the 6:00 AM and 6:40 AM buses are eliminated inbound and the 5:30 PM and 6:30 PM are eliminated outbound.

Based on the bus schedule, travel times for the Fall River bus route vary from 85 minutes during peak periods to 60 minutes during off -peak periods.

Taunton to Boston Bus Service

The Taunton to Boston commuter bus service originates in Taunton at the GATRA/Bloom bus terminal and maintenance facility on Oak Street. The service has two official stops along the route to Boston: Raynham/Taunton Greyhound Track park-and-ride lot on Route 138 in Raynham and Route 106 near Route 24 overpass park-and-ride lot in West Bridgewater. Other flag stops are offered at the Friendly's restaurant on Route 138 and at the corner of Route 138/Route 106 in Easton. If requested, the inbound trip will stop at the Westgate Mall in Brockton. Based on requests for stops, the outbound trip includes up to four stops at the Westgate Mall throughout the day as needed.

Taunton to Boston service differs from the Fall River and New Bedford services as it does not use South Station Bus Terminal. The Taunton service has street rights to drop-off/pick-up passengers on street at Park Square at 212 Stuart Street and near South Station at the corner of Lincoln Street/Kneeland Street inbound, and at the corner of Lincoln Street/Beach Street, outbound. Figure 3.2-6 depicts the Taunton bus route to Boston.

The Taunton bus terminal has recently been upgraded with a new paved parking lot, new lot striping, and new lighting. There was also a new pedestrian walkway added down the center of the lot to link to the Oak Street sidewalks and emphasize pedestrian activity and multi-modal shared space at the terminal. The terminal parking lot has a capacity of 158 parking spaces, of which five are designated as handicapped parking.

GATRA has plans for terminal improvements identified in the fiscal year 2009-2012 TIP. The TIP does not indicate the nature or extent of the planned terminal improvements.

Taunton to Boston Bus Operations—The weekday schedule for the bus from Taunton to Boston provides 15 trips inbound and 14 trips outbound to Boston. The weekday inbound morning commute operates seven trips from 5:30 AM to 9:00 AM. The first five trips are on half-hour headways and the final two on 45-minute headways. The weekday outbound evening commute operates six trips from 3:35 PM to 7:05 PM. on various headways beginning with 45-minute headways, a 25-minute headway during peak period, back to a 45-minute headway and ending outbound service with 60-minute headways to the final bus at 7:05 PM.

Weekend commuter bus service is limited to two trips inbound and two trips outbound. During weekend service there is a 9:00 AM and 3:45 PM inbound trip and 9:50 AM and 4:55 PM outbound trip.

Based on the published schedule, travel times inbound range from 90 minutes during the peak periods to 60 minutes during the off- peak periods. Travel times outbound are consistent with times approximately 70 minutes throughout the day.

Commuter Park-and-Ride Lots for Bus Service from South Coast to Boston

Park-and-ride lots are located throughout the southeastern Massachusetts sub-region from Wareham to Attleboro. The following are the primary park-and-ride locations for buses to Boston, based on the MassHighway database and research of the study area:

- Route 106 near Route 24 – West Bridgewater, Massachusetts
- Route 24 Exit 12 – Silver City Galleria- Taunton, Massachusetts
- Oak Street Bloom/GATRA Terminal – Taunton, Massachusetts
- I-495 Exit 8 – Route 138/Greyhound Track – Raynham, Massachusetts
- Mt. Pleasant Street – New Bedford, Massachusetts
- 72 Sycamore Street – Fairhaven, Massachusetts

Figure 4.1-1 depicts the major park-and-ride locations in southeastern Massachusetts. The following section describes each park-and-ride location and existing capacity for each lot.

Route 106 near Route 24 – West Bridgewater Park-and-Ride Lot

This parking lot is located on the southwest corner of the Route 24/Route 106 interchange in West Bridgewater. The lot has a capacity of 140 vehicles and is in high demand during all times of the year. During recent parking surveys at this lot, many vehicles are illegally parked with overflow parking

exceeding capacity by five to 15 vehicles. Commuters can park here free and take the Bloom Bus to Boston. Bloom Bus drops-off/picks-up passengers at the corner of Pleasant Street and the southwest corner of the park-and-ride lot. The bus cannot circulate through the narrow parking lot so it stops just outside the lot at this location. Bus shelters are not provided at this lot. There are MassDOT plans to expand the park-and-ride lot by 40 parking spaces within the next five years.

Route 24 Exit 12 – Silver City Galleria – Taunton Park-and-Ride Lot

This parking lot is located within the main Silver City Galleria mall parking area as a separate small parking lot. The parking lot is designed as several rows of parking with a parking capacity for 187 vehicles that is near capacity in summer months based on field observations conducted in summer 2008.

The New Bedford bus serves this parking lot for the commute to Boston. Commuters can park here for free and take the New Bedford bus to Boston. The parking lot is designed so that buses can circulate the parking lot to pick-up/drop-off passengers. One small bus shelter is provided at the rear of the lot.

During a survey completed in October 2008 another new park-and-ride area was identified near the existing lot. This 24-space parking lot is located within the main mall parking area across the street from the main park-and-ride lot. It was signed and striped with red paint for park-and-ride use and was observed at full capacity during the survey.

Oak Street Bloom/GATRA Bus Terminal – Taunton Park-and-Ride Lot

This parking lot is attached to the Taunton bus terminal located on Oak Street in downtown Taunton, Massachusetts. The lot has a capacity of 158 parking spaces including five designated for handicapped commuters. Commuters can park here for free and take the Taunton bus to Boston. Based on historic parking utilization counts, the lot is underutilized with excess capacity during the typical weekday. Commuters board the buses via the rear of the terminal building at the bus bay. The terminal provides a ticket booth, café, and waiting area for passengers. Retail space is available for additional businesses.

Route 138 – Raynham/Taunton Greyhound Track – Raynham Park-and-Ride Lot

This parking lot is a small section of the overall Greyhound Track parking lot that has been designated for park-and-ride usage. There is no parking lot striping delineating the number of parking spaces. Based on data provided in the 2007 Southeastern Regional Planning Regional Transportation Plan, the capacity of this lot is 150 spaces. In June 2008 this lot was underutilized and partially being used for storage of telephone poles so the actual capacity may be less. There is one glass enclosed bus shelter at this park-and-ride.

Mount Pleasant Street – New Bedford Park-and-Ride Lot

This parking lot is a large surface lot with several rows of parking located off Mt. Pleasant Street, north of King's Highway in New Bedford. Based on a field visit to the site the lot has a capacity of 201 spaces, with five designated as handicapped parking. The lot is approaching capacity although there were a number of spaces available to the rear of the lot. The buses can access the parking lot easily and pick-up passengers at the two internal bus shelters. A field visit revealed illegal dumping occurring at the back of the site and drainage issues with large standing water occupying five parking spaces in the southeast corner of the parking lot. Due to the site design and depth of the parking lot from the street, there is concern about safety and security and a lack of adequate lighting.

72 Sycamore Street, DATTCO Bus Terminal – Fairhaven Park-and-Ride Lot

This parking lot is a small surface lot adjacent to the terminal. The lot has a capacity of 28 vehicles. Based on MassHighway data, this location has up to 80 spaces available. However, based on discussions with DATTCO these additional spaces are located in the fenced area located adjacent to the main terminal building and are no longer available due to safety and security concerns and should not be included in the total available parking. Based on recent parking surveys, there were available spaces to park in this small lot. Bus shelters are not provided at this lot but there is a covered overhang attached to the terminal that is used as a waiting area.

Bus Schedule Enhancements

Bus service plan and schedule enhancements are an essential part of improving commuter bus service to the South Coast study area. The current bus schedules from Taunton and New Bedford offer good service for the most part with reasonable headways based on their current schedules. The Fall River service requires schedule improvements to provide more inbound and outbound options that would offer shorter headways and enhanced commuter flexibility on arrival and departure times. The following sections summarize possible enhancements to the existing services.

Fall River Bus Service

The current Peter Pan commuter bus service for the Fall River to Boston commute is limited, with six inbound and six outbound trips. To offer better service and shorter headways, it is recommended that 30-minute headways be added to the schedule to enhance ridership during inbound and outbound peak periods to offer more flexible service for the Fall River commuters. During travel time surveys some Fall River commuters using the Taunton bus service (Bloom) indicated that the infrequent Peter Pan service is the reason they commuted via the Taunton bus service. The current schedule does not provide Fall River commuters with a flexible schedule and discourages ridership.

New Bedford Bus Service

The New Bedford commuter bus service (DATTCO) uses five buses constantly running throughout the day and provides 11 inbound trips and 11 outbound trips to South Station Bus Terminal. The service for the Boston commute offers a schedule similar to the Taunton service plan, although less extensive. There are 30-minute headways in the peak period direction. To enhance service, it is recommended that 30-minute bus headways for the evening commute begin at 4:00 PM and continue to 6:00 PM. This would require a minor adjustment to the existing schedule by including an additional bus for the evening commute. This schedule would offer more frequent service and shorter headways and provide more flexible service for New Bedford commuters.

Taunton Bus Service

The Taunton commuter bus service (Bloom) is extensive with 15 inbound trips and 14 outbound trips daily. This schedule provides 30-minute headways during the morning and evening peak period commuter times and is adequate for current demands. The addition of more buses for 15-minute headways during the peak period is not warranted at this time based on current ridership demands.

Park-and-Ride Lot Expansion/Bus Stations

The No-Build Alternative does not include any new or expanded park-and-ride lots or bus stations, and therefore the environmental impacts of any such expansions are not addressed in this FEIS/FEIR. Nevertheless, to be responsive to comments on the DEIS/DEIR requesting more information on the No-Build Alternative transportation conditions, information on locations potentially warranting expanded or new park-and-ride/bus station facilities are discussed below.

Based on parking utilization counts completed at the Silver City Galleria park-and-ride lot in Taunton in summer 2008, the existing lot is at capacity. During an October 2008 parking survey, additional parking was observed to have been established and was also filled to capacity. There are existing paved parking lots nearby that appear to be vacant. These lots could be used for a potential new expanded park-and-ride/bus station, or other sites could be identified in the immediate area around the Silver City Galleria and the Route 24/Route 140 highway interchange. A new facility at or near the mall could easily integrate local fixed route GATRA bus service which already serves the mall throughout the day. This linkage to local fixed route bus service could also encourage ridership on commuter bus.

Based on a review of available information and parking occupancy studies, a bus station/park-and-ride facility in the Bridgewater/West Bridgewater area, near the existing Route 106/Route 24 park-and-ride lot, would be readily utilized. A bus station and park-and-ride could be combined into one potential intermodal station near the existing park-and-ride lot. Both the existing park-and-ride lots at Route 106 (West Bridgewater) and Route 104 (Bridgewater) are operating at capacity. These two lots also do not allow buses to enter or exit the lots to pick-up or drop-off commuters. Although plans are underway to provide 40 more spaces at the West Bridgewater park-and-ride, a new park-and-ride/bus station could provide full bus access /egress and larger park-and-ride facilities. This might capture additional riders for all three commuter bus services that travel by this location via Route 24.

Based on review of available parking utilization studies for the Mt. Pleasant Street park-and-ride lot in New Bedford, this lot is operating at 80 percent of capacity. If future ridership projections for the area indicate a significant increase in ridership for this region, an expanded park-and-ride/bus station may have merit in the existing lot, on adjacent land, or at another suitable location in the general area.

Joint Ticketing System Bus/Rail

The commuter rail monthly fare provides a free ride on the MBTA bus or rapid transit for those commuters that purchase monthly passes. This service is a significant advantage to commuter rail versus private commuter bus, as the bus companies do not offer this benefit, making bus travel less attractive to commuters.

SRPEDD and the commuter bus operators have advocated for transportation policymakers to address the transit fare inequity between modes with a joint ticketing system allowing the bus operators to offer the same pass as commuter rail with free access to MBTA bus and rapid transit. A joint ticket for commuter bus would enhance bus service to the region.

3.2.3.3 South Station Expansion Project

One of the rail improvements anticipated to be undertaken under No-Build condition is the expansion of South Station. MassDOT, with funding from the Federal Railroad Administration (FRA), is undertaking a project to evaluate the expansion of Boston’s South Station. The South Station Expansion project includes planning, NEPA/MEPA reviews, and preliminary engineering. The South Station Expansion

project is being undertaken to allow for expansion of intercity and high-speed rail (HSR) service into Boston's South Station, and to improve existing rail operations and service delivery at South Station provided by the National Railroad Passenger Corporation (Amtrak) and the MBTA.[15] The key elements of the South Station Expansion Project include:

- Expand the South Station terminal facilities, including the addition of up to seven tracks and platforms and construction of a new passenger concourse and other amenities.
- Acquire and demolish the U.S. Postal Service (USPS) General Mail Facility located on Dorchester.
- Avenue adjacent to South Station, which will provide an approximate 16-acre site onto which to expand South Station.
- Create an extension of the Harborwalk along reopened Dorchester Avenue.
- Provide for the possibility of future joint/private development adjacent to and over an expanded South Station.
- Provide adequate rail layover space to address existing and future intercity and commuter rail service needs. Currently, there are not sufficient train layover facilities to meet existing South Station operational requirements, resulting in restrictive scheduling of revenue and non-revenue trains in and out of South Station. To accommodate existing needs and to facilitate future Amtrak and MBTA service expansions and other planned improvements, additional layover space is required. The three sites currently under consideration are the Boston Transportation Department-owned Tow Lot, Beacon Park Yard, and Readville-Yard 2.

As described in the South Station Expansion ENF and federal funding application, the increase in South Station capacity and the midday layover facility is needed for both existing and future operations of both Amtrak and MBTA. Expansion of South Station has independent utility (40 CFR 1508.25(a)) from the South Coast Rail project because, while it would be required to accommodate any of the commuter rail alternatives of the South Coast Rail project, the need for expansion of South Station capacity exists without the South Coast Rail project and the expansion of South Station would be constructed absent the construction of other projects in the project area. The expansion of South Station will be subject to its own environmental review process, which is ongoing. The South Station Expansion DEIR is anticipated in summer 2014.

3.2.4 Stoughton Electric Alternative

The Stoughton Electric Alternative would provide commuter rail service to South Station using the Northeast Corridor (NEC), Stoughton Line, New Bedford Main Line, and Fall River Secondary. The New Bedford route would be 55.0 miles long and the Fall River route would be 52.7 miles long. Figure 3.2-7 shows the route of the Stoughton Alternative.

The Stoughton Alternative would:

- Utilize 15.5 miles of existing NEC track infrastructure between Boston and Canton Junction (no new track infrastructure would be required along this 15.5-mile length of the NEC);

[15] http://www.massdot.state.ma.us/Portals/25/Docs/efs/EnvironmentalNotificationForm.pdf

- Require improvements to track infrastructure along the Stoughton Line including:
- Reconstructing existing tracks from Canton Junction to Stoughton, as double track, a distance of 3.8 miles; and
- Constructing new tracks on existing right-of-way from Stoughton Station to Longmeadow Road in Taunton, as one to two tracks, a distance of 14.9 miles;
- Require reconstructing track from Longmeadow Road to Weir Junction in Taunton, from one to two tracks, a distance of 1.7 miles;
- Require reconstructing track on the Southern Triangle (common to both the Stoughton and Whittenton Alternatives), including:
- Reconstructing the existing New Bedford Main Line tracks from Weir Junction to New Bedford, as two to three tracks from Weir Junction to Myricks Junction, a distance of 4.9 miles; and single track with three sidings from Myricks Junction to New Bedford, a distance of 14.5 miles; and
- Reconstructing the existing Fall River Secondary tracks from Myricks Junction to Fall River, as single track with four sidings, a distance of 12.3 miles.
- Infrastructure improvements for the Stoughton Alternative also include constructing, reconstructing, or widening 40 bridges and constructing or reconstructing 46 railroad at-grade crossings. A summary of the Stoughton Alternative is provided in Tables 3.2-2 and 3.2-3.

Table 3.2-2 Summary of Alternatives—Track

	Stoughton Alternative			Whittenton Alternative		
Segment	**Length (miles)**	**Number of Tracks**	**Number of Sidings**	**Length (miles)**	**Number of Tracks**	**Number of Sidings**
Canton to Stoughton Station	3.8	2		3.8	2	
Stoughton Station to Weir Junction	16.4	1-2		17.9	1-2	1
Weir Junction to Myricks Junction	4.9	2-3		4.9	2-3	
Myricks Junction to New Bedford	14.5	1	3	14.5	1	3
Myricks Junction to Fall River	12.3	1	4	12.3	1	4
Total Length (South Station to New Bedford)	55.0			56.6		
Total Length (South Station to Fall River)	52.7			54.3		

Table 3.2-3 Summary of Alternatives—Crossings

Alternatives	Bridges	At-Grade Crossings
Stoughton	40[1]	46[2]
Whittenton	38[1]	53[2]

[1] Does not include existing bridges that would not require reconstruction
[2] Includes private crossings

This alternative would have ten new commuter rail stations (North Easton, Easton Village, Raynham Park, Taunton, Taunton Depot, King's Highway, Whale's Tooth, Freetown, Fall River Depot, and Battleship Cove) and major reconstruction of two existing commuter rail stations (Canton Center and

Stoughton). This alternative would include two overnight layover facilities, one in New Bedford and one in Fall River.

To support electric locomotives, a traction power system would be built and would include two main substations (one in Easton and one in New Bedford), two switching stations (one in Canton and one in Berkley), and six paralleling stations (one in Easton, one in Taunton, two in Freetown, one in New Bedford, and one in Fall River).

3.2.5 Stoughton Diesel Alternative

The Stoughton Diesel Alternative would be identical to the Stoughton Electric Alternative with the exception of the electrical facilities, which would not be required for the diesel alternative.

3.2.6 Whittenton Electric Alternative

The Whittenton Alternative would provide commuter rail service to South Station through Stoughton, connecting to the existing Stoughton Line using the Whittenton Branch and a short segment of the Attleboro Secondary through the City of Taunton. Figure 3.2-8 shows the Whittenton Alternative. The New Bedford route would be 56.6 miles long and the Fall River route would be 54.3 miles long.

The Whittenton Alternative would:

- Utilize 15.5 miles of existing NEC track infrastructure between Boston and Canton Junction;
- Require improvements to track infrastructure along the Stoughton Line, including:
    - Reconstructing existing tracks from Canton Junction to Stoughton, as double track, a distance of 3.8 miles; and
    - Constructing new tracks on existing right-of-way from Stoughton to Raynham Junction, as one to two track sections a distance of 11.9 miles;
- Require constructing new single track on existing Whittenton Branch right-of-way from Raynham Junction in Raynham to Whittenton Junction;
- Require reconstructing existing Attleboro Secondary tracks from Whittenton Junction to Weir Junction, as a single track with one siding, a distance of 6.0 miles);
- Require reconstructing track on the Southern Triangle (common to both rail alternatives) including:
    - Reconstructing the existing New Bedford Main Line tracks from Weir Junction to New Bedford, as two to three tracks from Weir Junction to Myricks Junction, a distance of 4.9 miles; and single track with three sidings from Myricks Junction to New Bedford, a distance of 14.5 miles; and
    - Reconstructing the existing Fall River Secondary tracks from Myricks Junction to Fall River, as single track with four sidings, a distance of 12.3 miles.

Infrastructure improvements for the Whittenton Alternative also include constructing, reconstructing, or widening 38 bridges and constructing or reconstructing 53 railroad at-grade crossings. A summary of the Whittenton Alternative is provided in Tables 3.2-2 and 3.2-3.

This alternative would have ten new commuter rail stations (North Easton, Easton Village, Raynham Park, Dana Street, Taunton Depot, King's Highway, Whale's Tooth, Freetown, Fall River Depot, and Battleship Cove) and major reconstruction of two existing commuter rail stations (Canton Center and Stoughton), as well as expansion of South Station. This alternative would include two overnight layover facilities, one in New Bedford and one in Fall River.

To support electric locomotives, a traction power system would be built and would include two main substations (one in Easton and one in New Bedford), two switching stations (one in Canton and one in Berkley), and six paralleling stations (one in Easton, one in Taunton, two in Freetown, one in New Bedford, and one in Fall River).

3.2.7 Whittenton Diesel Alternative

The Whittenton Diesel Alternative would be identical to the Whittenton Electric Alternative with the exception of the electrical facilities, which would not be required for the diesel alternative.

3.2.8 Operations of the Rail Alternatives

This section provides a description of the major components of the Stoughton and Whittenton Alternatives. Specific topics addressed are Operations, Track Infrastructure, Grade Crossings, Bridges and Culverts, Signals and Communications, Rolling Stock, Electrification, & Diesel, Stations, Layover Facilities, and Cost.

Operations of the South Coast Rail alternatives were evaluated and modeled to optimize travel times and ridership. Based on this effort, the operating plan was revised to include a zone-express type operating pattern. In the DEIS/DEIR, all trains made all stops from Fall River/New Bedford to South Station. Under the revised operating plan, peak-period trains between New Bedford and Boston would stop at all stations between Whale's Tooth and North Easton, but would skip the Stoughton, Canton Center, and Canton Junction stations. Trains operating between Fall River and Boston during the peak periods would stop at Battleship Cove, Fall River Depot, Freetown, and all stops from North Easton to Boston. Peak period Fall River trains would not stop at Easton Village, Raynham Park, Taunton (Dean Street Station for the Whittenton Alternatives), or Taunton Depot stations. This change in operations results in reduced trip times for both the Fall River and New Bedford trains which is used for the 2035 ridership projections.

The following sections describe the existing operations on the NEC, Stoughton Line, Fall River Secondary, and New Bedford Main Line, as well as the proposed operating plans for both the South Coast Rail alternatives, and the station stopping patterns.

3.2.8.1 Existing Operations

The NEC, Stoughton Line, Attleboro Secondary, Fall River Secondary, and New Bedford Main Line all currently provide some element of freight or passenger service. The following sections describe the existing passenger and freight operations along these alignments. The Whittenton Branch, which would be utilized for the Whittenton Alternative, does not provide any freight or passenger service at this time. Figures 3.2-9 and 3.2-10 show the existing rail transportation system and its ownership.

Northeast Corridor

The MBTA, Amtrak and CSX operate over the NEC within the state of Massachusetts. The MBTA owns the line, but it is dispatched by Amtrak from their South Station Centralized Electric and Traffic Control facility. That facility exchanges data between Metro North Railroad Operations Control Center, the MBTA Operations Control Center, and Amtrak's Penn Station Control facility.

The NEC between Providence and Readville is predominately a two track electrified (25 kV 60 Hz) Class 8 railroad that is authorized at speeds up to 150 mph where civil infrastructure permits. Currently, only Amtrak reaches speeds above 79 mph on this section of the NEC. The MBTA commuter rail currently operates using diesel locomotives (F40s) with speeds up to 79 mph. CSX operates freight service predominately south of Mansfield.

Over the past two decades a multitude of operational studies have been completed reviewing the type, amount, and frequency of service that can be provided in this section of the NEC. All of these studies agree that this is a very congested portion of the NEC and that the addition of high-speed service has reduced the reserve capacity on the NEC. This reduction in reserve capacity is amplified by the great discrepancy in operating speeds between the different types of service on the corridor.

The MBTA operates five commuter lines on the NEC between South Station and the state line. Each line branches off the corridor, with the exception of the Providence Line service which travels the entire NEC in the state of Massachusetts. The MBTA uses diesel locomotives with up to eight bi-level or single level coaches. The MBTA's maximum authorized speed on the NEC is 79 mph and 70 mph off of the NEC where civil infrastructure conditions permit. The five branch lines include the Worcester Line, Needham Line, Franklin Line, Stoughton Line, and Providence Line. The existing (2008) service for these lines is summarized in Table 3.2-4.

Table 3.2-4 Existing (2008) MBTA and Amtrak Rail Operations

Passenger Service	AM Peak	PM Peak	Off Peak NB	Off Peak SB	Total NB Trips	Total SB Trips
Worcester	8	7	15	13	21	20
Needham	5	5	11	11	16	16
Franklin	7	6	12	12	19	18
Stoughton	4	5	9	12	17	17
Providence	8	5	9	14	20	19
Amtrak	1	3	13	14	19	19

Note: Short turn trains counted

Stoughton Line, Attleboro Secondary, Fall River Secondary, New Bedford Main Line

Passenger rail operations dominate existing railroad operations on the Stoughton Line. There is only one existing freight train that typically operates in a window of availability between Stoughton Line passenger services during the off-peak afternoon period.

The existing freight service for the South Coast Region is shared between CSX Transportation (CSX) and the Massachusetts Coastal Railroad (MCRR). CSX operates on the Attleboro Secondary and Middleboro Secondary. MCRR operates on the Fall River Secondary, New Bedford Main Line, a section of the Attleboro Secondary, and on the Stoughton Line in Taunton. CSX operates long haul freight service and

transfers cars with MCRR at Attleboro, Cotley Junction, and Middleborough. CSX dispatches these lines from its Selkirk, New York dispatch center.

3.2.8.2 FEIS/FEIR Proposed Operations

The Stoughton and Whittenton Electric Alternatives have similar operating plans. The plans were developed to meet the current minimum requirements of the MBTA Service Delivery Plan for commuter rail. The infrastructure proposed for each alternative has been designed to support these levels of operation.

Commuter Rail Operations

The proposed operations would have four peak period trains to each of the terminal stations of New Bedford and Fall River. This translates to approximately 30-minute service on both the Fall River Secondary and the New Bedford Main Line, and an 18 minute headway on the trunk (shared) portion of the route north of Myricks Junction. During the off-peak periods, six additional trains would operate on a 3 hour frequency from the terminal stations and 90 minutes on the trunk portion. This provides 10 round trip trains per weekday from each terminal station.

Both commuter rail alternatives would use the same station stops south of Taunton Depot. By employing a zone-express service pattern (where trains stop at a few stations and then run express), travel times for passengers traveling from Fall River and New Bedford would decrease as compared to those presented in the DEIS/DEIR. Table 3.2-5 summarizes the proposed station stopping pattern for each of the alternatives.

Table 3.2-6 summarizes the total trip time from each terminal station (New Bedford and Fall River) to South Station based on the station stopping pattern in Table 3.2-5. These trip times are between 5 and 7 minutes faster than shown in the DEIS/DEIR due to the revised service plan. As shown in Table 3.2-6, the Stoughton Electric Alternative would be 6 to 7 minutes faster than the Whittenton Electric Alternative for service to New Bedford, and 8 minutes faster for service to Fall River.

The average trip times in Table 3.2-6 are based on simulation of the Stoughton Electric Alternative. Diesel alternatives would add approximately 20 seconds per station due to the additional time diesel locomotives need to accelerate from the stations and their lower maximum speeds. Deceleration rates would be identical to those of the electric alternatives. It is noted that although its operating plan skips a few stops, the peak period service has a longer travel time due to longer dwell times at each station in order to load and unload the higher numbers of passengers using the service during peak commuting hours. The off-peak period service would stop at every station but would have much shorter dwell times and would, therefore, have a slightly shorter average travel time than the peak service.

Table 3.2-5 Proposed Stopping Patterns (Stoughton and Whittenton Alternatives)

	Stoughton Alternative				Whittenton Alternative			
	Fall River Line		New Bedford Line		Fall River Line		New Bedford Line	
Station	Peak	Off-Peak	Peak	Off-Peak	Peak	Off-Peak	Peak	Off-Peak
Battleship Cove								
Fall River								
Freetown								
Whale's Tooth								
Kings Highway								
Taunton Depot								
Dana Street								
Taunton								
Raynham Park								
Easton Village				1				1
North Easton								
Stoughton								
Canton Center								
Canton Junction								
Route 128[2]								
Hyde Park[2]								
Ruggles[2]								
Back Bay								
South Station								

1 One train in the evening would not stop at Easton Village.

2 Stopping patterns vary at Route 128, Hyde Park and Ruggles. Existing service to Route 128, Hyde Park and Ruggles stations does not stop every Providence and Stoughton train at these stops. The Stoughton Electric Alternative would provide additional opportunity to connect to these stations with a service to New Bedford and Fall River. The operating plan proposed seven additional morning peak period stops at Route 128, four additional morning stops at Hyde Park and three additional at Ruggles. The evening peak service would generally remain unchanged.

Table 3.2-6 Average Trip Time Table, Stoughton and Whittenton Electric Alternatives (hr:min)

	Stoughton Electric Alternative		Whittenton Electric Alternative	
Operation	New Bedford Trains	Fall River Trains	New Bedford Trains	Fall River Trains
Peak Period Service	1:17	1:15	1:24	1:23
Non-Peak Period Service	1:16	1:18	1:22	1:26

1 Overall travel times for each branch of the Stoughton and Whittenton Electric Alternatives were developed using the Rail Traffic Controller model.
2 Assumptions were made based on track and signal layout.
3 Express trains may have longer travel times than local trains since they only operate during peak periods.

Feeder Bus

The Feeder Bus plan for the South Coast Rail project is envisioned to connect the urbanized communities in the study area to the South Coast stations. A Feeder Bus network would provide an alternative to driving to stations and would support transit oriented development and other smart growth initiatives in the study area by connecting surrounding areas to the train station. The Feeder Bus network would provide frequent, convenient service connections with trains.

Three regional transit authorities currently provide local bus service within the region: Brockton Area Transit Authority (BAT), Southeastern Regional Transit Authority (SRTA) and Greater Attleboro Taunton Regional Transit Authority (GATRA). The SRTA and GATRA operators use a fleet of buses that accommodate bicycles, which would encourage multi-modal integration for the South Coast Rail project. Current bus operators would provide enhanced Feeder Bus service to the proposed stations for the selected Build Alternative. On February 8, 2012, a meeting was hosted by SRPEDD with representatives of each of the bus operators to review a draft version of the feeder bus plan and receive their input on the proposed plan. The following objectives guided the development of the plan:

- Identify potential route modifications to existing bus routes to integrate South Coast Rail and local bus services to the extent possible;
- Minimize the number of transfers required by transit riders to use the South Coast Rail system;
- Limit route modifications to the extent possible to avoid inconveniencing current bus users;
- For stations served by bus, accommodate buses within the station site and as close as possible to the station platforms; and
- Plan for ADA compliant pedestrian connections to bus stops adjacent to the station sites and within the South Coast Rail station sites.
- Feeder Bus service would connect the South Coast Rail stations with the services shown in Table 3.2-7. Further details on the decisions made in selecting these stations and service changes are provided in the Feeder Bus Service Analysis Report, Appendix 3.2-Aof this FEIS/FEIR.

Table 3.2-7 Proposed Feeder Bus Operations

Station Name	Operator	Route #	Extension Length (miles)	Existing Headway (minutes)	Proposed Peak Frequency
Easton Village	BAT	8	3.0	40	same
Taunton Station	GATRA	7	0.4	30	same
Dana Street Station	GATRA	18	0.3	30	same
Taunton Depot	GATRA	8	0.2	60	same
Freetown Station	SRTA	2	1.0	30	same
Fall River Depot	SRTA	2	0.4	20	same
Kings Highway	SRTA	8	0	45	same
Whale's Tooth	SRTA	1	0.7	20	same
Whale’s Tooth	SRTA	2	0	20	same

3.2.8.3 Layover Facility Operations

The following sections describe midday and overnight layover facility operations.

Midday Facilities

The South Coast Rail project would require midday storage in the Boston area, and would utilize the same midday layover facilities that are envisioned for the planned expansion of South Station. For the purpose of the operations simulations, all South Coast Rail trains are assumed to enter and leave the system over the Fort Point Channel Bridge. The operation simulations have been conducted by modeling these movements to identify any impacts that might occur to the NEC and South Station. As discussed above in Section 3.2.3.3, the South Station Expansion Project (including the layover facility component) has independent utility from the South Coast Rail project because it is necessary to meet future demand regardless of whether or not the South Coast Rail project is constructed and operated.

Overnight Layover Facilities

Both of the commuter rail alternatives would require overnight layover facilities along the Fall River Secondary and New Bedford Main Line. The preferred locations for these facilities are near the terminal stations to minimize non-revenue movements. A layover facility has been selected for each of the terminal stations – these locations are identified in Section 3.2.16. Trains either completing or initiating revenue runs would need to change ends (engineer walks through train to operate from other end), perform the required brake tests, and then proceed north into the layover facility. It is estimated that this movement would consume approximately 10 to 15 minutes, but would not reduce main line capacity.

Freight Operations

Although future freight demand was not modeled as part of the project, future operating windows for freight trains were included. Freight trains would be allowed to operate on the sections of track listed in Table 3.2-8, during the times specified. Each segment provides at least 10 hours per day of freight operations, typically in 1-hour windows during the day. These windows will allow existing freight customers to continue to receive goods via freight train service and eliminate conflicts between freight and passenger train operations.

Table 3.2-8 Freight Operating Windows

Time of Day From	To	Length of Window
Canton Junction to Stoughton Center (CSX)		
9:06:52	10:09:00	1:02:08
10:37:24	11:39:02	1:01:38

22:37:08	0:16:50	1:39:42
0:43:51	5:09:42	4:25:51
Total Freight Operating Window Time		14:04:16
Weir Junction South to Cotley Junction (CSX and MCRR)		
9:15:46	10:01:28	0:45:42
10:42:56	11:30:32	0:47:36
12:15:46	13:01:39	0:45:53
13:45:17	14:32:41	0:47:24
20:23:39	21:22:28	0:58:49
22:32:05	0:23:51	1:52:41
0:47:23	5:06:23	4:19:00
Total Freight Operating Window Time		10:17:05

Time of Day From	To	Length of Window
Myricks Junction to Fall River (MRCC)		
8:35:45	10:45:47	2:10:02
11:27:46	13:48:08	2:20:22
14:29:55	16:48:37	2:18:42
20:20:00	22:10:00	1:50:00
23:04:58	0:50:14	1:45:16
1:20:34	4:53:06	3:32:32
Total Freight Operating Window Time		13:56:54
Myricks Junction to New Bedford (MCRR)		
7:35:53	9:18:20	1:42:27
9:58:40	12:18:20	2:19:40
12:58:51	15:20:20	2:21:29
15:58:20	17:33:08	1:34:48
20:21:38	21:25:57	1:04:19
22:03:20	0:27:20	2:24:00
1:05:24	4:33:26	3:28:02
Total Freight Operating Window Time		14:54:45

Freight service would be restricted to standard freight size and weight, and would not support high-and-wide or double-stack operations where it does not currently provide high-and-wide or double-stack operations. Freight services is anticipated to continue on the track segments where freight is currently provided (on the Stoughton Line north of Stoughton Station, on the Attleboro Secondary, on the Stoughton Line in Taunton between Longmeadow Road and Weir Junction, and on the New Bedford Main Line and Fall River Secondary south of Weir Junction). No future freight service is currently

planned or anticipated on the currently out-of-service Whittenton Branch or Stoughton Line between Stoughton Station and Longmeadow Road.

3.2.8.4 Fare Collection

Fare collection for the commuter rail alternatives would be the same as the existing MBTA commuter rail lines. Fares would be collected on board the trains by conductors. Passengers would have the option to purchase individual tickets on board the trains or purchase single ride, multiple ride, or monthly passes from the MBTA or retail sites.

3.2.9 Track Infrastructure of the Rail Alternatives

Subsequent to the DEIS/DEIR, MassDOT has advanced the preliminary track design for the Stoughton Alternative and the Whittenton Alternative. All track changes have been minor. The design of bridge structures has been advanced, particularly for the Hockomock Trestle between Foundry Street and the Raynham Greyhound Park.

The FEIS/FEIR track layout for the Stoughton Alternative varies from the track layout included in the DEIS/DEIR in the following ways:

- A proposed north end double track on the New Bedford Main Line was cut back from Pig Farm Road to Tarkiln Hill Road;
- In the DEIS/DEIR, a passing siding was added on the Fall River Secondary near the Fall River Golf Club; and a siding was proposed from Freetown to Fall River Depot Station. This has since been changed to three separate sidings in an effort to reduce environmental impacts while maintaining operational flexibility. The sidings would be located at Freetown Station, near the Fall River Golf Club, and at the Fall River Depot Station;
- Weir Junction was reconfigured to provide 45 mph operations through the curve;
- A short second track was added at Battleship Cove; and
- A passing siding for freight trains was added at Taunton Depot Station.

3.2.9.1 FEIS/FEIR Track Design

All of the rail alternatives require reconstructing existing active tracks and constructing new tracks either on abandoned or new rights-of-way. The new track infrastructure would consist of new 132RE rail, new rail ties, new stone ballast, subballast and other track material. The horizontal and vertical geometry for the new track has been designed to conform to the applicable design speed for the alternatives in accordance with the MBTA commuter rail design standards and American Railway Engineering and Maintenance-of-Way Association design standards. The alignments have also been designed to minimize impacts to adjacent environmental resources and private properties. The proposed track typical sections are shown in Figures 3.2-1 and 3.2-2 (for the diesel alternatives) and 3.2-3 through 3.2-5 (for the electric alternatives).

3.2.9.2 Track Infrastructure—Stoughton Alternative

The New Bedford Main Line from Weir Junction in Taunton to the Whale’s Tooth Station, and the Fall River Secondary from Myricks Junction to Battleship Cove Station, are segments of track common to

both commuter rail alternatives as is the track from Raynham Junction to South Station. Only the segment from Raynham Junction to Weir Junction would differ between the alternatives. Except in certain locations, the track would be designed for a maximum authorized speed (MAS) of 100 MPH. Locations which would be designed for less than 100 MPH MAS would be at certain sidings (which would be too short to achieve 100 MPH), and south of the King's Highway Station, where it would be precluded by single track operations.

Stoughton Line

The existing single track commuter rail line would be upgraded and maintained to FRA Class 7. A new second track would be constructed from Canton Junction to the existing Stoughton Station, where existing passenger service ends. A new double track would extend south of Stoughton Station to the proposed North Easton Station. The remainder of the line south to Weir Junction would be single- track, with a 2.2-mile long double-track section in Raynham, and a 0.6 mile long double-track section in Taunton. Approaching Weir Junction, an additional 0.4 mile siding track would be provided for freight use only. Weir Junction would also be reconfigured to accommodate four tracks as well as 45 MPH for operations through the curve while maintaining existing rail connections. These track segments are listed in Table 3.2-9.

A frontage road would be constructed in Stoughton connecting to Morton Street to eliminate multiple grade crossings, and a new grade-separated crossing is proposed at Route 138 in Raynham. A trestle section is proposed in Easton and Raynham to minimize environmental impacts to the Hockomock Swamp Area of Critical Environmental Concern.

Table 3.2-9 Track Infrastructure – Stoughton Alternative

Track Segment	Single Track	Double Track	Triple Track	Quadruple Track	Total (miles)
Canton Junction to Stoughton Station[1]	-	3.8	–	–	3.8
Stoughton Station to Raynham Junction[1]	7.1	4.8	–	–	11.9
Raynham Junction to Weir Junction[1]	2.9	1.1	–	0.4	4.5
Weir Junction to Cotley Junction[2]	–	0.7	0.9	–	1.6
Cotley Junction to Myricks Junction[2]	–	3.3	–	–	3.3
Myricks Junction to Battleship Cove[3]	9.4	2.9	–	–	12.3
Myricks Junction to Whale's Tooth[2]	10.1	4.5	–	–	14.5
TOTAL (miles)	**29.5**	**21.1**	**0.9**	**0.4**	**51.9**

1 Stoughton Line
2 New Bedford Main Line
3 Fall River Secondary

New Bedford Main Line

The 19.4-mile existing track along the New Bedford Main Line would be upgraded and maintained to FRA Class 7 options. The line would be double-track from Weir Junction to Myricks Junction, with a 0.9-mile third track for freight movements near Taunton Depot Station. A short segment of the line would be double-track south of Myricks Junction, 0.8 mile. The remainder of the line would be single-track, with the exception of 1.8-mile double-track section in Freetown and a 1.7-mile section in New Bedford. These sidings are required by the operations analysis and also allow flexibility between commuter and freight operations.

Fall River Secondary

The 12.3 miles of existing track along the Fall River Secondary would be upgraded and maintained to FRA Class 7 options. The majority of this line would be single-track with a 0.7 mile double-track segment at Myricks Junction. A 1.0-mile-long section of double track would be installed adjacent to the Fall River Golf Club. Three double-track sections are also proposed in Freetown and Fall River, at 0.6, 0.3, and 0.2 mile long, respectively, to allow flexibility between commuter and freight operations.

3.2.9.3 Track Infrastructure—Whittenton Alternative

The route for the Whittenton Alternative is similar to the Stoughton Alternative except in Raynham and Taunton. The New Bedford route would be 56.6 miles long and the Fall River route would be 54.3 miles long. This alternative would extend through the abandoned Stoughton Line, as previously described, and connect to the abandoned Whittenton Branch at Raynham Junction. The Whittenton Branch would extend south and west to the Attleboro Secondary at Whittenton Junction. Along the Attleboro Secondary, the Whittenton Alternative would extend to Weir Junction in Taunton. South of Taunton, the alternative would continue on the New Bedford Main Line and Fall River Secondary track, identical to the Stoughton Alternative.

Track infrastructure improvements would include 3.6 miles of new single-track on the Whittenton Branch and 2.2 miles of single-track reconstruction on the Attleboro Secondary with a 0.3-mile siding reserved for the proposed Dana Street Station. Improvements on the Stoughton Line between Canton Junction and Route 138 in Raynham would be the same as the Stoughton Alternative. Table 3.2-10 summarizes the track infrastructure improvements along the Whittenton Alternative.

Table 3.2-10 Track Infrastructure – Whittenton Alternative

Track Segment	Single Track	Double Track	Triple Track	Quadruple Track	Total (miles)
Canton Junction to Stoughton Station[1]	–	3.8	–	–	3.8
Stoughton Station to Raynham Junction[1]	7.1	4.8	–	–	11.9
Raynham Junction to Whittenton Junction[2]	3.6	–	–	–	3.6
Whittenton Junction to Weir Junction[3]	2.2	0.3	–	–	2.5
Weir Junction to Cotley Junction[4]	–	0.7	0.9	–	1.6
Cotley Junction to Myricks Junction[4]	–	3.3	–	–	3.3
Myricks Junction to Battleship Cove[5]	9.4	2.9	–	–	12.3
Myricks Junction to Whale's Tooth[4]	10.1	4.5	–	–	14.5
TOTAL (miles)	**32.4**	**20.3**	**0.9**	**0.4**	**53.5**

1 Stoughton Line
2 Whittenton Branch
3 Attleboro Secondary
4 New Bedford Main Line
5 Fall River Secondary

3.2.10 Grade Crossings

The majority of existing public grade crossings on the active railroad rights-of-way have automatic grade crossing gates and flashers installed. All existing grade crossings to remain and all reactivated crossings would be equipped with new, state-of-the-art Automatic Highway Crossing Warning (AHCW) systems. Trains would use horns when they approach grade crossings. Sounding a horn while approaching a grade

crossing is a well-proven and effective method of providing warning of an approaching train. MassDOT is not recommending Quiet Zones for noise mitigation and has committed to designing the South Coast Rail project grade crossings to the FRA safety standards.

Grade crossings would be closed or consolidated whenever feasible. Private grade crossings would be closed, gated, and locked if possible; if not, new AHCW systems would be installed. At a minimum each public grade crossing would consist of automatic gates, LED flashers, and an electronic bell. Where required, this standard arrangement may be supplemented with additional equipment such as additional gates and cantilevered flashers to optimize visibility for the roadway approaches.

The AHCW train detection would be based upon constant warning technology known as predictors. This system detects the speed of the train as it moves towards the crossing and “predicts” the arrival time. Each crossing would be set to provide a consistent 30 seconds of warning ahead of the train’s arrival at the crossing. The AHCW system would communicate with the MBTA Operational Control Center (OCC) through a dedicated Fiber Optic line that would be provided as part of the South Coast Rail project. This Fiber Optic line would allow MBTA train dispatchers to communicate with and receive indications directly from the AHCW system at each grade crossing.

Each crossing would be supported by a minimum 8-foot by 8-foot aluminum shed that would house the AHCW system. The houses would be placed at the most advantageous quadrant of the crossing to not impede sight distance of pedestrians, motorists, and train engineers.

Each crossing would require a power utility feed from the nearest commercial source. Additional or supplemental devices may require additional system infrastructure to support a particular application such as traffic preemption or advance active warning signs. Each AHCW system would be supported by storage batteries during times of power outages. These batteries would be housed in a separate box (battery well) located adjacent to the AHCW housing.

Table 3.2-11 is a summary of the number of grade crossings by alternative. Information on the improvements proposed for each crossing is provided in Chapter 4.1. See Figures 4.1-44 through 4.1-53 in Volume II for mapping of existing and proposed grade crossings.

Table 3.2-11 Summary of Public Grade Crossings by Alternative

Commuter Rail Alternative	Existing Active Grade Crossings	Existing Grade Crossings Recommended for Closure	Proposed New Grade Crossings[1]	Total Proposed Grade Crossings
Stoughton Alternative	31	3	15	43
Whittenton Alternative	40	3	13	50

1 Includes grade crossings that are existing but not active

3.2.11 Bridges and Culverts

All of the rail alternatives require reconstructing undergrade bridges (railroad over road or river) and overhead bridges (highway over railroad) along the active and restored rights-of-way.

The conditions of the existing railroad bridges were evaluated to determine each bridge’s current state of repair and whether the bridge can meet industry design standards. The bridges were also evaluated

to determine if it was feasible to install additional track where required for the rail operations. Based on this evaluation, the following recommended improvements were developed.

Existing culverts along the rail corridors would typically be replaced in-kind (or widened, as feasible and appropriate, for environmental enhancement) to resist increased loading and to accommodate the wider track bed where necessary.

3.2.11.1 Typical Railroad (Undergrade) Bridge Structure Types

The following bridge structure types are currently proposed for the undergrade bridges on the rail alternatives. The structure type considered for specific locations is dependent on span length, number of spans, structure depth constraints, cost and constructability. For overhead (roadway bridges), a detailed type study in accordance with MassDOT criteria would be performed during preliminary design to determine the most appropriate structure type.

Concrete Box Girder—Concrete box girder superstructures are primarily used for single span bridges with smaller spans up to approximately 25 feet in length (Figure 3.2-11). The box girders are placed adjacent to each other, providing a deck for the ballast and track. This minimizes field construction duration and associated impacts to track service. The open deck configuration allows for adjustability in track alignments which can be advantageous during construction staging.

Steel Tub—Steel tub superstructures are primarily used for single span bridges with spans ranging from roughly 25 feet to 60 feet in length (Figure 3.2-12). Ballast is placed onto a ballast plate deck, which is supported by longitudinal stringers and intermediate diaphragms. Much of the fabrication can be done in the shop, minimizing field construction times and associated impacts to track service. The open deck configuration allows for adjustability in track alignments which can be advantageous during construction staging.

Steel Thru Girder—Steel thru girder superstructures are primarily used for single or multiple span bridges with spans greater than 60 feet in length (Figure 3.2-13). Ballast is placed onto a ballast plate deck supported by floor beams and the main load carrying plate girders. Multiple track thru girder bridges utilize a shared plate girder between each set of tracks. This structure type minimizes structure depth for longer spans, although field construction is more time consuming than that for concrete box girder and steel tub superstructures. These structures do not allow for much adjustability in track alignment, in some instances making them difficult to stage.

3.2.11.2 New Bedford Main Line Railroad Bridges

Of the 18 bridges (both undergrade and overhead) on the New Bedford Main Line, nine would require rehabilitation or reconstruction as part of the South Coast Rail project. The bridges being replaced are either unable to meet the load requirements for the commuter rail, have open decks, are too narrow, or are recommended for replacement to reduce maintenance costs.

Several bridges originally carried two tracks. Currently, each bridge carries a single track. Four of the new bridges would be designed to carry two tracks, while the other five would still carry a single track. Many of the existing bridges have open timber decks. The new bridges would have solid decks on which ballast, ties, and rails would be placed.

Where the new bridge would have a longer span than the current structure, the new abutments would be located behind the old ones, the old ones would be demolished to the high water line (as currently

proposed), and the land between the old and new abutments restored to provide wildlife passage under the bridge. This condition exists at the Cotley River (MP 38.93 and MP 39.46), the Cedar Swamp River (MP 42.14), and Fall Brook (MP 45.43).

Where a new bridge would have an equal span to the current structure, the existing stone abutments would be rehabilitated and reused, if feasible. In some cases, the current bridge has multiple spans that the new bridge would replace with a single span, eliminating the mid-bridge piers required to support multiple spans. This occurs at Wamsutta Street (MP 54.21).

Table 3.2-12 provides a list of bridge crossings (both undergrade and overhead) and indicates which ones would require rehabilitation or reconstruction as part of the currently envisioned New Bedford Main Line segment of the South Coast Rail project. Appendix 3.2-B includes a description of the proposed work at each of the bridge locations.

Table 3.2-12 Summary of Bridges – New Bedford Main Line

Bridge	Municipality	Type	Mile Post	Improvements Required
Taunton River	Taunton	Undergrade	35.56	Yes
Brickyard Road	Taunton	Undergrade	35.79	Yes
Route 24	Taunton	Overhead	37.69	Yes
Cotley River	Berkley	Undergrade	38.93	Yes
Cotley River	Berkley	Undergrade	39.46	Yes
Cedar Swamp River	Lakeville	Undergrade	42.14	Yes
Howland Road	Lakeville	Overhead	43.26	No
Fall Brook	Freetown	Undergrade	45.43	Yes
Route 140	New Bedford	Overhead	50.66	No
Dean Street[1]	New Bedford	Undergrade	53.31	No
Sawyer Street[1]	New Bedford	Undergrade	53.57	No
Coggeshall Street[1]	New Bedford	Undergrade	53.67	No
Cedar Grove Street	New Bedford	Undergrade	53.79	No
I-195 Ramp	New Bedford	Overhead	53.81	No
Weld Street/Route 18 Ramp	New Bedford	Undergrade	53.95	No
Logan Street	New Bedford	Undergrade	54.01	No
Route 18	New Bedford	Undergrade	54.17	Yes
Wamsutta Street	New Bedford	Undergrade	54.21	Yes

1 Reconstructed in 2011-2012

3.2.11.3 Fall River Secondary Railroad Bridges

Of the 30 existing bridges (both undergrade and overhead) on the Fall River Secondary, 11 would require rehabilitation or reconstruction as part of the South Coast Rail project. One new bridge would be required (the Golf Cart Road pedestrian bridge). The bridges being replaced are either unable to meet the load requirements for the commuter rail, or are too narrow.

Five of the new bridges would be designed to carry two tracks, while the other seven would carry a single track. Many of the existing bridges have open timber decks. The new bridges would have solid decks on which ballast, ties, and rails would be placed. Where a new bridge would have an equal span to the current structure, the existing stone abutments would be rehabilitated and reused, if feasible. In

some cases the current bridge has multiple spans that the new bridge would replace with a single span, eliminating the mid-bridge piers required to support multiple spans. This would be the case for at the Cedar Swamp River (MP 41.51), Golf Club Road (MP 48.11), and President's Avenue (MP 51.11).

Table 3.2-13 provides a list of bridges (both undergrade and overhead) and indicates which ones would require construction, rehabilitation, or reconstruction as part of the currently envisioned Fall River Secondary segment of the South Coast Rail project. Appendix 3.2-B provides a description of the proposed work at each of the bridge locations.

Table 3.2-13 Summary of Bridges – Fall River Secondary

Bridge	Municipality	Type	Mile Post	Improvements Required
Cedar Swamp River	Freetown	Undergrade	41.51	Yes
Route 24/79	Freetown	Undergrade	45.58	No
South Main Street/Route 79	Freetown	Overhead	46.25	No
Farm Road	Freetown	Undergrade	46.63	Yes
Farm Road	Fall River	Undergrade	47.75	No
Golf Cart Road (Pedestrian)	Fall River	Overhead	47.90	New
Golf Club Road	Fall River	Overhead	48.11	Yes
Miller's Cove Road	Fall River	Undergrade	48.62	Yes
Clark Street	Fall River	Overhead	48.93	No
Collins Road	Fall River	Undergrade	49.06	Yes
Ashley Street	Fall River	Undergrade	49.21	Yes
Canedy's Underpass	Fall River	Undergrade	49.57	No
New Street	Fall River	Overhead	49.81	No
Western Expressway/Route 79	Fall River	Overhead	49.96	No
Western Expressway Ramps	Fall River	Overhead	50.06	No
Weaver Street	Fall River	Overhead	50.09	No
Cove Street	Fall River	Undergrade	50.43	No
Clinton Street	Fall River	Undergrade	50.49	No
Brightman Street	Fall River	Overhead	50.69	No
Brownell Street	Fall River	Undergrade	51.03	Yes
President's Avenue	Fall River	Undergrade	51.11	Yes
Pearce Street	Fall River	Undergrade	51.20	Yes
Turner Street	Fall River	Undergrade	51.40	Yes
Central Street	Fall River	Overhead	52.05	No
NB Ramp	Fall River	Overhead	52.05	No
SB Ramp	Fall River	Overhead	52.06	No
I-195	Fall River	Overhead	52.07	No
Route 138/Davol Street	Fall River	Overhead	52.09	No
Western Expressway, NB & SB	Fall River	Overhead	52.09	No
Anawan Street	Fall River	Overhead	52.19	No
Channel near Battleship Cove	Fall River	Undergrade	52.38	Yes

3.2.11.4 Stoughton Line Railroad Bridges

Of the 18 existing bridges (both undergrade and overhead) along the Stoughton Line, 14 would require rehabilitation or reconstruction as part of the Stoughton Alternative. The bridges being replaced are unable to meet the load requirements for the commuter rail.

Five completely new bridges are required. Three of the new bridges that pass over the rail right-of-way are in locations where previous bridges have been filled in (Main Street and Bridge Street in Easton and Thrasher Street in Taunton). At these locations the bridges would be constructed on new abutments or the existing abutments that remain, and the embankment excavated to track grade below. One new bridge would be built where none now exists (Route 138 Bridge, at MP 31.31 in Raynham) to provide a grade separation. The largest new bridge would be the trestle through the Hockomock Swamp with about 284 spans. It would be about 8,500 feet long and 24 feet wide at the level of the bridge deck. The structure would consist of multiple precast pre-stressed concrete superstructure spans on driven h-pile bent piers. Figure 3.2-14 shows the typical cross section of the trestle through the Hockomock Swamp. The basis for the trestle design and methods for construction are described in the Hockomock Swamp Trestle Technical Memorandum (Appendix 3.2-C).

The bridges listed for replacement have open timber decks (or none at all). The new bridges would have solid decks on which ballast, ties, and rails would be placed. Where the existing bridge abutments are stone, and the span length remains the same, the stonework may be rehabilitated and reused, if feasible. Two of the bridges that would be reconstructed would be built over existing stone masonry arched bridges (Forge Pond and Beaver Meadow Brook) to preserve these historic structures.

In some cases the current bridge has multiple spans that the new bridge would replace with two spans, eliminating the mid-bridge piers required to support multiple spans. This would be the case for at the Taunton River where the three bridges currently have 11 spans, 16 spans and 17 spans. Each would be replaced by a two-span bridge. The Taunton River bridges would be constructed to enhance wildlife passage by moving the abutments back from the riverbank.

Table 3.2-14 provides a list of bridge crossings (both undergrade and overhead) and indicates which ones would require rehabilitation or reconstruction as part of the currently envisioned Stoughton Alternative for the South Coast Rail project. Appendix 3.2-B provides a description of the proposed work at each of the bridge locations.

As required by the Secretary's Certificate on the DEIR, the feasibility of a trestle through the Pine Swamp was evaluated. As documented in Appendix 3.2-D, a trestle could be constructed through Pine Swamp but is not practicable based on cost, particularly when considered in the context of impacts to biological resources. Pine Swamp therefore does not have the extraordinary wildlife habitat value on both sides of the right-of-way that justifies the additional $45 million expenditure necessary to construct a trestle. The proposed mechanically stabilized reinforced earth stabilized track bed through the Pine Swamp along with other proposed mitigation including modifications to existing culverts and additional wildlife crossings provide a reasonable cost-effective solution to reduce the barrier effect resulting from replacing the former tracks that is in keeping with the biological diversity and overall value of the Pine Swamp.

Table 3.2-14 Summary of Bridges – Stoughton Line

Bridge	Municipality	Type	Mile Post	Improvements Required
Revere Street	Canton	Undergrade	15.21	No
Forge Pond	Canton	Undergrade	15.79	Yes
Bolivar Street	Canton	Undergrade	16.11	Yes
Mill Brook (also called Beaver Meadow Brook)	Canton	Undergrade	16.56	Yes
Coal Yard Road	Stoughton	Undergrade	19.07	Yes
Totman Farm Road	Stoughton	Undergrade	20.85	Yes
Day's Farm Road (private)	Easton	Undergrade	21.57	Yes
Cowessett Brook (also called Whitman Brook)	Easton	Undergrade	21.75	Yes
Ames & Pond Streets	Easton	Undergrade	22.80	Yes
Small Creek (also called Queset Brook)	Easton	Undergrade	22.84	Yes
Main Street	Easton	Overhead	22.93	New
Bridge Street	Easton	Overhead	23.27	New
Hockomock Swamp Trestle	Easton	Undergrade	27.00 to 28.60	New
Bridge Street	Raynham	Overhead	30.20	Yes
I-495	Raynham	Overhead	30.48	No
Route 138	Raynham	Overhead	31.31	New
Thrasher Street	Taunton	Overhead	33.33	New
Taunton River	Taunton	Undergrade	34.38	Yes
Taunton River	Taunton	Undergrade	34.38	Yes
Taunton River	Taunton	Undergrade	34.73	Yes
Summer Street	Taunton	Overhead	34.80	No
Mill River	Taunton	Undergrade	34.90	Yes
High Street	Taunton	Overhead	35.00	No

3.2.11.5 Whittenton Alternative Bridges and Culverts

The Whittenton Alternative would require all of the bridge work described for the Stoughton Alternative with the exception of six bridges. These include Route 138 in Raynham, Thrasher Street, the three Taunton River bridges in Taunton, and the Mill River Bridge in Taunton (the Whittenton Alternative crosses the Mill River at a bridge upstream from the Stoughton Alternative crossing). The Whittenton Alternative would also require rehabilitation or reconstruction of all three of the existing bridges on the Whittenton Branch. A new bridge would replace the bridge that once spanned King Phillip Street. The existing stacked stone abutments do not provide adequate lateral or vertical roadway clearance. A new superstructure and abutments would be constructed to provide clearances in accordance with current standards including travel lanes and sidewalks. The Bay Street Bridge was recently filled in and would need to be reconstructed to provide adequate track clearance for the rail service. A new superstructure would be constructed on new abutments and the embankment fill excavated below to the proposed track grade. The Mill River Bridge associated with the Whittenton Alternative is now a five span structure; it would be replaced by a two-span bridge carrying a single track. The existing abutments would be demolished and the new abutments constructed behind the existing abutments. The existing abutments would then be demolished down to the high water level and the space between the old and new abutments graded to recreate the stream banks under the bridge.

Table 3.2-15 provides a summary of the bridges along the Whittenton Branch. Appendix 3.2-B provides a description of the proposed work at each of the bridge locations.

Table 3.2-15 Summary of Bridges – Whittenton Alternative

Bridge	Municipality	Type	Mile Post	Improvements Required
King Phillip Street	Taunton	Undergrade	30.38	New
Bay Street	Taunton	Overhead	31.58	Yes
Mill River	Taunton	Undergrade	32.16	Yes

3.2.11.6 Summary of Bridge Improvements

Table 3.2-16 provides a summary of bridge improvements for the Stoughton and Whittenton Alternatives. The table is a general summary of the required bridge work among the alternatives. The summary includes existing bridges to be reconstructed and new bridges required to restore/provide grade separation or traverse sensitive areas.

Table 3.2-16 Summary of Bridge Improvements by Alternative

Commuter Rail Alternative	Reconstruct Undergrade (Railroad) Bridges	Reconstruct Overhead (Highway) Bridges	New Bridges for Grade Separation or Environmental
Stoughton Alternative	31	3	6
Whittenton Alternative	29	4	5

3.2.12 Signals and Communications

The Signals and Communications design remains the same as described in the DEIS/DEIR. The following sections summarize the design and compare the Stoughton and Whittenton Alternatives.

3.2.12.1 Signals and Communications—General Overview

The rail alternatives require a new signal system throughout, with the exception of the NEC. The new signal systems would be required to include Positive Train Control (PTC) as mandated by Congress in the Rail Safety Act of 2008; the new signal system would be capable of stopping the train (“positive stop”) if the train engineer fails to operate the vehicle as directed by the signal system. For the purposes of this document, it has been assumed that the new signal system would be the same as the existing signal system technology implemented on the NEC. The FRA has already deemed this system compliant with the Act. The NEC system is a cab-based signal system, meaning that the signal and the allowable speed are presented to the engineer in the cab of the locomotive.

The communications system would include a new fiber optic conduit. This would allow the signal system and grade crossings to be connected to the MBTA OCC. The communications system would also connect the MBTA OCC to systems at station stops, including passenger warning, public information and address, security, fire alarm, and police call back systems. Provisions would be made for future expansion of systems, such as for fare collection.

3.2.12.2 Stoughton Alternative Signals and Communications

The Stoughton Alternative requires a new PTC signal system for the New Bedford Main Line, Fall River Secondary, and the Stoughton Line. Modifications to the existing NEC signal system are limited to updating the signal logic at the Junction Interlocking. These minor improvements would be needed to make the signal logic on the corridor consistent with the signal logic of the new system on the Stoughton Line.

3.2.12.3 Whittenton Alternative Signals and Communications

The Whittenton Alternative requires a new PTC signal system for the New Bedford Main Line, Fall River Secondary, Attleboro Secondary, Whittenton Branch, and Stoughton Line. Modifications to the existing NEC signal system are limited to updating the signal logic at the Junction Interlocking. These minor improvements would be needed to make the signal logic on the corridor consistent with the signal logic of the new system on the Stoughton Line.

3.2.13 Rolling Stock

Both the Stoughton and Whittenton Alternatives would use commuter rail technology on a fixed-guideway system with steel wheels operating on steel rails, with typically a single locomotive pulling (outbound) or pushing (inbound) a number of passenger coaches. On the MBTA system, coaches can be either single level or bi-level. Commuter rail trains would be powered by diesel or electric locomotives, depending on the alternative. The electric locomotives would be powered by a 25 kV/60 Hz overhead contact system (OCS). The diesel alternative would not require an OCS.

3.2.13.1 Coaches

Commuter rail trains would consist of eight coaches. The coaches would be either single level or bi-level if additional capacity is needed. The MBTA currently uses coaches manufactured by Bombardier, Kawasaki, Messerschmitt-Bolkow-Blohm and Pullman Standard BTC. Existing coaches on the MBTA system are rated for a top operating speed of 90 MPH. It is anticipated that modified versions of these same coaches would be used for electric operations to achieve a 100 MPH rating. This would not be required for diesel operations that would operate at a top operating speed of 79 MPH. Single level coaches can carry 125 to 130 passengers and bi-level coaches can carry 175 to 185 passengers.

3.2.13.2 Locomotives

There are three differences between diesel and electric locomotives that are noteworthy. First, electric trains have higher performance characteristics, particularly in terms of quicker acceleration. Second, top travel speeds differ: for diesel-powered commuter rail, the maximum speed is assumed to be 79 mph, the maximum current operating speed on the MBTA system; for electric commuter rail, the maximum speed is assumed to be 100 MPH, which is the maximum speed that can be operated without incurring significant signal costs. Electric locomotives require an overhead wire (a catenary) to distribute power to the electric locomotive. The MBTA does not currently have electric locomotives in their commuter rail system, though some diesel powered trains travel on the electrified NEC.

The following is a description of the diesel and electric locomotives:

Electric Locomotives

- Type – HHP-8 manufactured by Bombardier or similar

- Acceleration performance is better than diesel locomotives
- Top Travel Speed – 125 MPH
- Fuel – electric using an 25 kV/60 Hz overhead wire (catenary) to distribute power to the electric locomotive

Diesel Locomotives

- Type – F40PH's manufactured by EMD or similar
- Acceleration performance is less than electric locomotives
- Top Travel Speed – 103 mph
- Fuel – diesel or bio-diesel

Table 3.2-17 summarizes the number of new coaches and locomotives required for each commuter rail alternative. Figure 3.2-15 depicts the typical diesel and electric locomotives.

Table 3.2-17 Rolling Stock Requirements[1]

Alternatives	Locomotives	Coaches	Cab Cars
Stoughton	10	72	10
Whittenton	10	72	10

1 Includes spare locomotive, coaches, and cab cars since the MBTA currently does not have electric locomotives.

3.2.14 Electrification System

A new traction electrification system is required to provide electric power to locomotives for the electric commuter rail alternatives. The diesel alternatives would not require these infrastructure improvements.

The new traction electrification system would tie into the existing NEC electrification system with some modifications to that system. The traction electrification system would provide power to the trains from wayside traction power facilities through an OCS that distributes the power to the trains' pantographs. The pantographs, mounted on the roof of the rolling stock, would collect the electrical power from the OCS through mechanical contact by sliding under the OCS contact wire. The electrical circuit would be completed back to the source substation via multiple return paths, including running rails and static wires.

Three major elements would make up the traction electrification system:

- Traction Power System, which include traction power substations, switching stations and paralleling stations. Figure 3.2-16 illustrates a typical Traction Power Station.
- Overhead Contact System (OCS), which distributes the electrical power to the rolling stock, and includes the messenger and contact wires, and the associated supporting structures and

hardware. The track negative feeder wires are considered associated with the OCS. Figure 3.2-17 illustrates a typical OCS.

- Traction Power Return System, which makes up the running rails, impedance bonds and static wires.

The traction power system and OCS are described below.

3.2.14.1 Traction Power System

The traction power system would provide a network of electric traction power facilities that transform power from the utility power grid at 115 kV to the 25 kV voltage required by electric locomotives. The power is distributed from the traction power facilities to the trains via the OCS. For South Coast Rail, the proposed traction power system would be similar to the one currently in use on the NEC between New Haven, CT and Boston, Massachusetts, in order to take advantage of this existing infrastructure. This system is a 2x25 kV autotransformer alternating current system requiring three types of traction power facilities:

- **Main Substations (AKA Traction Power Substations)—**that draw power from the utility power grid. They are typically located near high voltage, overhead transmission lines. A typical main substation site is 150 feet by 200 feet.

- **Switching Stations—**here two sections of the traction power system powered from different main substations meet. Electricity can be distributed to different sections, and different sections can be energized, de-energized, isolated or interconnected. They are typically mid-way between main substations and switching station sites can be as large as 60 feet by 150 feet.

- **Paralleling Stations—**that are between main substations and switching stations, spaced about 6 miles apart. They allow sections to be connected in parallel. They contain less equipment than the main substation and switching stations and require a 40-foot by 80-foot site.

- **Wayside Power—**provide power and remote control of interlocking lighting and OCS disconnect switches. Wayside power locations are also used to power other systems such as signals and lighting. The wayside power cubicle, which would house much of the equipment, would be located at interlocking.

The traction power system would include two main substations (one in Easton and one in New Bedford), two switching stations (one in Canton and one in Berkley), and six paralleling stations (one in Easton, one in Taunton, two in Freetown, one in New Bedford, and one in Fall River). A switching station would be required at the point where the Stoughton and Whittenton Alternatives join with the NEC. Figures 3.2-18 through 3.2-19 show the Traction Power System for the Stoughton and Whittenton Alternatives.

3.2.14.2 Overhead Contact System

The OCS would be a network of catenary wires that distributes power from the traction power system to electric locomotives. This system would have a contact wire and a messenger wire strung above every electrified track in the system, negative feeder wires and static wires and supporting structures to hold the catenary wire in place. The support system for the catenary would consist of pole structures with foundations, poles, guys, insulators, brackets, cantilevers, and other assemblies and components. For

the South Coast Rail project, there would be three types of catenary supports: single-track cantilever poles, twin-track cantilever structures and multiple track portals.

3.2.15 Stations

Station locations have remained as shown in the DEIS/DEIR, with the exception of the Stoughton Station and Downtown Taunton Station. Stoughton Station was relocated to eliminate grade crossing conflicts with traffic in Stoughton Center and to support downtown revitalization efforts. A discussion is provided of the site options considered for Stoughton Station relocation. Downtown Taunton Station as described in the DEIS/DEIR was replaced by Dana Street Station, due to development of the originally selected site near the GATRA bus terminal since the publication of the DEIS/DEIR. The Dana Street site was chosen as a replacement for the Downtown Taunton station site since it is a sizable vacant parcel along the right-of-way and is proximate to the previously selected Downtown Taunton site.

Station layout, parking, grading, and drainage designs for the North Easton, Raynham Park, Taunton, Taunton Depot, and Freetown locations have been advanced since completion of the DEIS/DEIR.

3.2.15.1 Station Description

New commuter rail stations generally would consist of high-level platforms, canopies, commuter parking, and a pick-up/drop-off area for buses and “kiss & ride” that conform to MBTA Commuter Rail Station design criteria and the Americans with Disabilities Act (ADA). High-level platforms would be constructed at a height that is 4 feet above the top-of-rail level, allowing for level-boarding onto all the commuter rail coaches for a 9-car train set (approximately 800 feet long). Platform configurations (i.e., side platform or center island platform) are dependent on the number of tracks, operations, and existing site constraints.

Most of the new commuter rail parking lots were sized to accommodate the park and ride ridership projected by CTPS for the particular station, plus a 20 percent increase to meet the 2030 parking demand and potential future growth. However, two of the station parking areas were designed to provide parking space counts that differ from the unconstrained park and ride projections. Taunton Station was designed with fewer spaces than the ridership model projected. Although there would be sufficient area to provide the required parking, the number of parking spaces was constrained to provide an area that could be used for transit-oriented development opportunities to improve the economic conditions of the local communities. The second commuter rail parking lot with a different design than projected demand levels was the Taunton Depot Station parking lot. This station would have more spaces than the projected demand in order to capture the ridership that might be unable to find adequate parking at Taunton Station, because these stations would be in close proximity to each other and Taunton Station was designed with constrained parking.

Local roads and parking lots would also be impacted due to installation of additional tracks/platforms. Existing parking and access drives have been replicated as closely as possible to avoid major disruption to existing stations and communities.

It is a goal of the project that the new commuter rail station designs would include amenities such as bike storage areas, pedestrian connections to neighboring streets/developments (where applicable), and commuter-related services such as newspaper stands and payment boxes. The MBTA would also explore implementing green technologies such as solar panels, Energy Star-compliant products, and environmentally friendly designs to the maximum extent practicable. Stations are intended to function

similarly to the majority of existing MBTA commuter rail stations; they would be unattended and would require self-pay parking. The proposed stations would not include station buildings, and water/sewerage facilities would not be required.

3.2.15.2 Station Sites

This section provides a description of each proposed station, including a general site description, number of parking spaces, platform description, driveway access, and bus/kiss & ride accommodations. A summary of the stations is provided in Table 3.2-18. Stormwater management and drainage designs for each station are described in Chapter 4.17, *Water Resources*.

Table 3.2-18 Summary of Stations

Station Name	Municipality	Station Type	Parking Spaces	Platform Type[4]	Stoughton Alternative	Whittenton Alternative
Canton Center	Canton	Existing	210 [1]	Side (2,Low)	x	x
Stoughton	Stoughton	Relocated	636	Side (2)	x	x
North Easton	Easton/Stoughton	New	501	Center Island	x	x
Easton Village	Easton	New	0 [2]	Side	x	x
Raynham Park	Raynham	New	432	Center Island	x	x
Taunton	Taunton	New	210	Side	x	-
Taunton Depot	Taunton	New	398	Center Island	x	x
Freetown	Freetown	New	173	Side	x	x
Fall River Depot	Fall River	New	518	Side	x	x
Battleship Cove	Fall River	New	0 [2]	Side	x	x
King's Highway	New Bedford	New	360 [3]	Side	x	x
Whale's Tooth	New Bedford	New	748	Side	x	x
Dana Street	Taunton	New	477	Side	-	x
TOTAL – NEW STATIONS					**10**	**10**
TOTAL – MODIFICATIONS TO EXISTING STATIONS					**2**	**2**

1 Existing lot
2 Pick up/Drop off only
3 Shared parking
4 All platforms are single high-level unless denoted otherwise

Canton Center

Canton Center Station is an existing station site off of Washington Street that would be modified to accommodate a second track (Figure 3.2-20). Two new 800 foot long low-level platforms with mini-high platforms would be constructed (one adjacent to each track). Modifications to the tracks and platforms would require minor changes to the parking layout in the existing lots near the station, and no adjustments to the amount of existing parking spaces would be expected. This station would continue to serve walk-in, bike-in and drive-in customers. The Canton Center Station design is summarized as follows:

- Parking Spaces – approximately 210 existing parking spaces would remain.

- Parking Lot Type – existing paved surface parking.
- Station Access Drive – driveway access from Washington Street.
- Bus/Kiss & ride Accommodations – no designated areas for bus or kiss & ride.
- Platform Type – two side platforms.
- Platform Dimension – 800-foot low-level platforms, 9.5 to 12 feet wide with mini-high platforms.
- Track Configuration – double track.
- Pedestrian Accommodations – a walkway would be installed from each platform to existing sidewalks along the Washington Street.
- Stormwater Management – existing drainage would remain.

Stoughton

The Stoughton Station would be relocated as part of the South Coast Rail project to eliminate conflicts with traffic in Stoughton Center and to meet regulatory requirements for access. Relocating the station would also be consistent with downtown revitalization efforts.

The existing Stoughton Station is currently the terminal station on the Stoughton Branch of the MBTA commuter rail service. At the current station location, stopped trains block the Wyman Street at-grade crossing while passengers board and alight the train. This situation has contributed to congestion in downtown Stoughton. Expanding commuter rail service to the South Coast will require modifications to this station to accommodate a second track, which would exacerbate the traffic congestion at the Wyman Street at-grade crossing under the current station configuration. The low-level platforms of the current station do not meet Americans with Disabilities Act (ADA) accessibility requirements and must be replaced by a high-level platform.

The DEIS/DEIR described the station relocation south towards Brock Street, out of the Wyman Street at-grade crossing. The crossing gates at Wyman Street would be deactivated while trains dwell at the station, allowing traffic to pass through the downtown area with fewer interruptions. At the location proposed in the DEIS/DEIR, the station would be on a track curve and, due to spatial constraints of train cars on the curve, would need to maintain low-level platforms with "mini high" sections to allow persons with disabilities to enter or exit the cars. However, low-level platforms with mini-high platforms do not meet current ADA accessibility requirements that stipulate high-level platforms at all new or reconstructed stations, where possible.

MassDOT analyzed four location options (with one additional variation); each option relocates the station south of the current Wyman Street at-grade crossing and provides high-level platforms to meet ADA accessibility requirements. The options are described below and summarized in Table 3.2-19.

- **Option 1**—Realign tracks and relocate station between Wyman Street and Brock Street with high-level platforms and parking on both sides of the tracks. This option is close to downtown. It would require acquisition of 0.3 acre of residential and 9.5 acres of industrial or commercial

properties, vertical circulation for access (a pedestrian bridge), and one connection across the tracks (via the pedestrian bridge). The estimated cost of this option would be $16 million.

Table 3.2-19 Stoughton Station Options

Option	Description	Cost ($M)
1	-Realign tracks and relocate station between Wyman Street and Brock Street with high-level platforms and parking on both sides of the tracks. -Close to downtown -Requires acquisition of 0.3 acre of residential and 9.5 acres of industrial or commercial properties, vertical circulation for access, and one connection across the tracks.	16
2	-Realign tracks and relocate station between Wyman Street and Brock Street with high-level platforms and parking on both sides of the tracks. -Close to downtown and has two means of crossing the tracks. -Requires acquisition of 0.2 acre of residential and 9.6 acres of industrial or commercial properties.	16
3	-Realign tracks and relocate station north of Brock Street with high-level platforms and parking on the west side of the tracks. -Close to downtown, opens 2.5 acres of land for potential development, and has two means of crossing the tracks. -Requires acquisition of up to 0.2 acre of residential and 9.6 acres of industrial or commercial properties, and vertical circulation.	16
3A	-Realign tracks and relocate station north of Brock Street with high-level platforms and structured parking on the west side of the tracks. -Close to downtown, opens 1.4 acres of land for potential development, has two means of crossing the track, and the second level of the garage provide easier access across the pedestrian bridge. -Requires acquisition of 0.2 acre of residential and 9.6 acres of industrial or commercial properties, and vertical circulation.	38
4	-Realign tracks and relocate station south of Brock Street with high-level platforms. -Does not require a pedestrian bridge, opens 1.2 acres of land for potential development. -Farthest from downtown, requires pedestrian crossings at Brock Street, impacts an on-site wetland and intermittent stream, and requires acquisition of 0.2 acre of residential property and 7.7 acres of industrial or commercial properties.	13

- **Option 2**—Realign tracks and relocate station between Wyman Street and Brock Street with high level platforms and parking on both sides of the tracks. This option is close to downtown and has two means of crossing the tracks (pedestrian bridge and at-grade crossing). It would require acquisition of 0.2 acre of residential and 9.6 acres of industrial or commercial properties. The estimated cost of this option would be $16 million.

- **Option 3**—Realign tracks and relocate station north of Brock Street with high level platforms and parking on the west side of the tracks. This option is close to downtown, would open 2.5 acres of land east of the tracks for potential development, and has two means of crossing the tracks (pedestrian bridge and at-grade crossing). It would require acquisition of up to 0.2 acre of residential and 9.6 acres of industrial or commercial properties, and vertical circulation (pedestrian bridge). The estimated cost of this option would be $16 million.

- **Option 3A**—Realign tracks and relocate station north of Brock Street with high level platforms and structured parking on the west side of the tracks. This option is the same as Option 3 except with the addition of a parking structure, which would allow for development on part of the parcel that would be used for surface parking under Option 3. It is close to downtown, opens 1.4 acres of land east of the tracks for potential development, has two means of crossing the track (pedestrian bridge and at-grade crossing), and the second level of the garage would provide

easier access across the pedestrian bridge. It would require acquisition of 0.2 acre of residential and 9.6 acres of industrial or commercial properties, and would require vertical circulation (pedestrian bridge). The estimated cost of this option would be $38 million due to the high cost of the parking structure.

- **Option 4**—Realign tracks and relocate station south of Brock Street with high level platforms. This option does not require a pedestrian bridge, opens 1.2 acres of land east of the tracks for potential development and requires fewer takings than the other options; this option is also the least expensive of the build options. It would be the farthest from downtown (via a 0.25-mile pedestrian path), would impact an on-site wetland and intermittent stream, would require pedestrian crossings at Brock Street to access the platforms, and would require acquisition of 0.2 acre of residential property and 7.7 acres of industrial or commercial properties. The estimated cost of this option would be $13 million.

Each option was reviewed with regard to operations and accessibility to select a station location and configuration that would meet operational and regulatory requirements and provides benefits to the community at a reasonable cost. Four options were eliminated from further consideration:

- Options 1 and 2, which provide parking on both sides of the tracks, were not favored because they would require vertical circulation (stairs/elevators). Keeping the parking on one side of the tracks, with the platform close to Brock Street, would make it less likely that vertical circulation would be required.

- Option 3A, which includes a parking garage, was not favored because of the high project cost. However, locating parking on the west side of the tracks under Option 3 does not preclude a future parking garage. Locating parking only on the west side of the tracks would also open up development opportunity for the downtown, including the Rose Street extension.

- All the alternatives require some land acquisition. Option 4 requires the least land acquisition but would require pedestrians to cross both the Brock Street at grade crossing and the Brock Street traffic flow to access the station from the parking area west of the track. Option 4 would also impact an on-site wetland and intermittent stream to accommodate the parking lot and stormwater storage area. This option was not favored.

The remaining option—Option 3—was advanced for analysis in the FEIS/FEIR as it would provide the best balance of cost and convenience of the options considered. Figure 3.2-21 shows the Stoughton Station relocation site plan. The existing Stoughton Station would be relocated from its present location between Porter and Wyman streets to a new location south of the Wyman Street at-grade crossing, where it would accommodate a second track. Two new 800-foot-long, full-length high-level platforms would be constructed (one adjacent to each track). A pedestrian bridge with stairs and ramps would connect the two platforms. These modifications to the tracks and platforms would require a new parking layout to the west of the platforms. This station would continue to serve walk-in, bike-in and drive-in customers. The Stoughton Station design is summarized as follows:

- Parking Spaces – a new parking lot on the west side of the tracks would provide 636 total spaces consisting of 17 handicapped accessible and 619 standard spaces.

- Parking Lot Type –paved surface parking.

- Station Access Drive – main driveway access on the south side from Brock Street and also on the west side from Morton Street.
- Bus/Kiss & ride Accommodations – a 100-foot pick-up/drop-off area would accommodate up two 40-foot buses and provide a waiting area for kiss & ride.
- Platform Type – two side platforms with a pedestrian bridge (stairs and ramps).
- Platform Dimension – 800-foot high-level platforms, 12 feet wide.
- Track Configuration – double track.
- Pedestrian Accommodations – sidewalks would be constructed at the northern end of each platform connecting to existing sidewalks. South of the platforms, pedestrians may utilize the existing at-grade pedestrian crossing at Brock Street. A pedestrian bridge provides a link between the inbound and outbound platforms.
- Stormwater Management – space has been reserved for an infiltration basin and drainage would tie in to the municipal system.

North Easton

North Easton Station would be located in Stoughton and Easton at the rear of the Roche Brothers Plaza off of Route 138 (Figure 3.2-22). This existing retail plaza is anchored by Roche Brothers supermarket and recently constructed medical buildings. This station would primarily serve drive-in customers, although the station may attract some walk-in customers from the existing development in the plaza and from some nearby residences. The North Easton Station design is summarized as follows:

- Parking Spaces – 501 total spaces consisting of 10 handicapped accessible and 491 standard spaces.
- Parking Lot Type – paved surface parking.
- Station Access Drive – driveway access from Roche Bros. Way.
- Bus/Kiss & ride Accommodations –110-foot pick-up/drop-off area that would accommodate two 40-foot buses and 5 kiss & ride parking spaces.
- Platform Type – one center platform with a pedestrian bridge (stairs and ramps).
- Platform Dimension – 800-foot high level platform, 22 feet wide.
- Track Configuration – double track.
- Pedestrian Accommodations – a sidewalk would be installed along the access road that would connect with an existing sidewalk along Roche Bros. Way.
- Feeder Bus – there are no feeder bus connections envisioned for this station.

- Stormwater Management – stormwater would be collected and treated on site. The majority of runoff at this site would be directed to one of four infiltration basins. Runoff from the northern portion of the parking lot would flow to a bioretention basin.

Easton Village

Easton Village Station would be located immediately south of the historic Old Colony Railroad station that is part of the H.H. Richardson National Historic Landmark and is located along Sullivan Street in Easton (Figure 3.2-23). The site is within walking distance of downtown Easton and would be a village-style station serving walk-in and bike-in customers. The existing Old Colony Railroad Station now houses the Easton Historical Society and includes a small parking facility that would be partially reconfigured for pick-up/drop-off traffic flow through the lot. A small number of the spaces in the existing lot would be designated for kiss & ride. The Easton Station design is summarized as follows:

- Parking Spaces – no commuter parking would be provided, though some spaces in an existing private lot would be designated for kiss & ride.
- Parking Lot Type – kiss & ride only.
- Station Access Drive – existing driveway access from Mechanic Street and new exit to Mechanic Street.
- Bus/Kiss & ride Accommodations – no accommodation for buses is proposed within the existing lot. An existing parking facility would provide approximately 12 kiss & ride spaces and a new exit would be constructed to improve traffic flow through the lot.
- Platform Type – one side platform.
- Platform Dimension – 800-foot high-level platform, 10 feet wide.
- Track Configuration – single track.
- Pedestrian Accommodations – a ramp from the northern end of the platform down to Oliver Street would convey pedestrians to an existing sidewalk on Oliver Street. A ramp near the southern end of the platform down to an existing pedestrian underpass (under the tracks) would connect to an existing sidewalk on Sullivan Street.
- Feeder Bus – A Stonehill College shuttle would be provided and the existing BAT Route 9 would be extended.
- Stormwater Management – existing drainage conditions would be maintained.

Raynham Park

Raynham Park Station would be located adjacent to the Raynham-Park Simulcast Center (formerly, the Raynham-Taunton Greyhound Park) off of Route 138 (Figure 3.2-24). The station would serve walk-in, bike-in and drive-in customers. The Raynham Park Station design is summarized as follows:

- Parking Spaces – 432 total spaces consisting of 10 handicapped accessible and 422 standard spaces.

- Parking Lot Type – paved surface parking.
- Station Access Drive – access from Route 138 through the existing complex to station area.
- Bus/Kiss & ride Accommodations – independent access driveway leading to a 110-foot pick-up/drop-off area that would accommodate two 40 foot buses and kiss & ride.
- Platform Type – one center platform with a pedestrian bridge (stairs and ramps).
- Platform Dimension – 800-foot high level platform, 22 feet wide.
- Track Configuration – double track.
- Pedestrian Accommodations – walkways would be added in conjunction with future transit oriented development.
- Feeder Bus – there are no feeder bus connections envisioned for this station.
- Stormwater Management – stormwater would be collected and treated on site. Runoff would be directed to a bioretention basin to the north of the site or bioretention swale south of the site.

Taunton (Stoughton Alternative)

Taunton Station would be located along Arlington Street near Dean Street (Route 44), adjacent to the historic Old Colony Railroad Station that currently serves an existing real estate business (Figure 3.2-25). The City of Taunton has begun the process of remediating this brownfield site in anticipation of a future train station. The site is within walking distance of downtown and would be utilized for future transit-oriented development. The station would serve walk-in, bike-in and drive-in customers. The Taunton Station design is summarized as follows:

- Parking Spaces – 210 total spaces consisting of 8 handicapped accessible and 202 standard spaces.
- Parking Lot Type – paved surface parking.
- Station Access Drive – driveway access from Arlington Street.
- Bus/Kiss & ride Accommodations – a 110-foot pick-up/drop-off area would accommodate up two 40-foot buses and provide a waiting area for kiss & ride. Wide aisles and adequate turning radii provide a bus route through the parking lot.
- Platform Type – one side platform.
- Platform Dimension – 800-foot high level platform, 12 feet wide.
- Track Configuration – single track (with a freight siding).
- Pedestrian Accommodations – walks would be installed from the platform along the access driveway out to Arlington Street for future walkway connections.

- Feeder Bus – reroute GATRA Route 7 for access to the station; reroute GATRA Routes 6 and 18 for better transfer access at Taunton Green.

- Stormwater Management – stormwater would be collected and treated on site. Runoff would be directed to a bioretention basin. A perforated underdrain would convey treated water to the municipal system.

Taunton Depot

Taunton Depot Station would be located off of Route 140 in Taunton at the rear of a shopping plaza that contains Target, Home Depot, and other stores (Figure 3.2-26). This station would serve walk-in, bike-in and drive-in customers. The Taunton Depot Station design is summarized as follows:

- Parking Spaces – 398 total spaces consisting of 9 handicapped accessible and 389 standard spaces.

- Parking Lot Type – paved surface parking.

- Station Access Drive – driveway access through the existing Target Plaza off of Route 140 connecting with a new driveway behind the Target to the new station parking area.

- Bus/Kiss & ride Accommodations –a 155-foot pick-up/drop-off area would accommodate up to three 40-foot buses and provide a waiting area for kiss & ride. Wide aisles and adequate turning radii provide a bus route through the parking lot.

- Platform Type – one center platform with a pedestrian bridge over the tracks (stairs and ramps).

- Platform Dimension – 800-foot high-level platform, 22 feet wide.

- Track Configuration – triple track (two for commuter rail adjacent to the platform and one freight track not adjacent to the platform).

- Pedestrian Accommodations – a sidewalk would be installed adjacent to the proposed access driveway out through the Target Plaza, connecting with the existing sidewalk on Taunton Depot Drive.

- Feeder Bus – The existing GATRA Route 8 would be extended a short distance to provide a stop at the station.

- Stormwater Management – stormwater would be collected and treated on site. Runoff would be collected in three lined bioretention basins.

Freetown Station

Freetown Station would be located on South Main Street (Figure 3.2-27). The site is currently occupied by a self-storage business, and is near the Fall River Executive Park and the proposed Riverfront Business Park. The station would serve drive-in customers and customers shuttled between the station and the industrial parks. The area around the site has been considered for future transit oriented development. The Freetown Station design is summarized as follows:

- Parking Spaces – 173 total spaces consisting of 7 handicapped accessible, and 166 standard spaces.
- Parking Lot Type – paved surface parking.
- Station Access Drive – driveway access off South Main Street.
- Bus/Kiss & ride Accommodations – a 110-foot pick-up/drop-off area would accommodate up two 40-foot buses and provide a waiting area for kiss & ride. Wide aisles and adequate turning radii provide a bus route through the parking lot.
- Platform Type – one side platform.
- Platform Dimension – 800-foot high-level platform, 16 feet wide.
- Track Configuration – double track.
- Pedestrian Accommodations – sidewalks would be installed from the platform out to South Main Street for future walk connections.
- Feeder Bus – The existing SRTA Route 2 would be extended 1 mile to the proposed station.
- Stormwater Management – stormwater would be collected and treated on site. Runoff is directed to infiltration basins.

Fall River Depot

Fall River Depot Station would be located 1 mile north of downtown Fall River at Route 79 and Davol Street at the site of the former train station (Figure 3.2-28). A proposed parking deck would be installed at this location to limit surface parking and provide space for future transit-oriented development. This station would serve walk-in, bike-in and drive-in customers. The Fall River Depot Station design is summarized as follows:

- Parking Spaces – 518 total spaces consisting of 11 handicapped accessible and 507 standard spaces.
- Parking Lot Type – paved surface parking with a one-level parking deck.
- Station Access Drive – driveway access from Davol Street and Pearce Street.
- Bus/Kiss & ride Accommodations – independent access driveway that would accommodate up to four 40-foot buses and 10 kiss & ride parking spaces.
- Platform Type – one side platform.
- Platform Dimension – 800-foot high-level platform; 12 feet wide.
- Track Configuration – double track.

- Pedestrian Accommodations – sidewalks would be installed along the frontage of Davol, Pearce, and Turner Streets connecting to existing sidewalks in the vicinity of the site. Sidewalks would be extended through the site and connect with ramps and stairs for platform access.

- Feeder Bus – Pedestrian access would be improved providing a connection to SRTA Route 2; reroute SRTA Route 14 to access the station;

- Stormwater Management – stormwater would be collected by catch basins which would tie in to the municipal system.

Battleship Cove

Battleship Cove Station would be located behind the Ponta Delgada monument along Water Street in Fall River (Figure 3.2-29). The station is a platform-only station that would not operate year-round. Serving the downtown and the Battleship Cove tourist area, the station is planned to accommodate walk-in and pick-up/drop-off customers. The City of Fall River constructed the Ponta Delgada monument, which includes a pick-up/drop off loop road, in anticipation that this site would be utilized as a commuter rail station. Work on Battleship Cove Station would need to be coordinated with the Route 79 construction project that is proposed by MassDOT's Highways Division (MassHighways). The Battleship Cove Station design is summarized as follows:

- Parking Spaces – pick-up/drop-off only.

- Parking Lot Type – pick-up/drop-off area on existing paved loop driveway.

- Station Access Drive – driveway access off Water Street.

- Bus/Kiss & Ride Accommodations – the paved loop driveway would accommodate up to three 40-foot buses and passenger vehicles for pick-up and drop-off of commuter rail passengers.

- Platform Type – one side platform.

- Platform Dimension – 800-foot high-level platform, 12 feet wide.

- Track Configuration – single track.

- Pedestrian Accommodations – a walkway would be installed from the platform to existing sidewalks along the pick-up/drop-off loop road.

- Feeder Bus –SRTA Routes 6 and 7 were rerouted in May 2012 to better serve the Battleship Cove area.

- Stormwater Management – existing drainage would be maintained.

King's Highway

King's Highway Station would be located in northern New Bedford south of King's Highway, immediately east of Route 140 (Figure 3.2-30). This station would occupy part of a site that is an existing shopping plaza. The station would serve walk-in, bike-in, and drive-in customers. The King's Highway Station design is summarized as follows:

- Parking Spaces – 360 total existing spaces consisting of 12 handicapped accessible and 348 standard spaces. Spaces would be shared with existing retail (movie theater) uses.
- Parking Lot Type – existing paved surface parking (shared).
- Station Access Drive – access from King's Highway through existing shopping complex to shared parking area and pick-up/drop-off area.
- Bus/Kiss & Ride Accommodations – 115-foot pick-up/drop-off area would accommodate up to two 40-foot buses and provide a waiting area for kiss & ride.
- Platform Type – one side platform.
- Platform Dimension – 800-foot high-level platform, 12 feet wide.
- Track Configuration – double track.
- Pedestrian Accommodations – a ramp would be installed at the northern end of the platform down to a sidewalk that would be extended adjacent to the tracks northward to connect into existing sidewalks on King's Highway.
- Feeder Bus –SRTA Route 8 provides service to the station.
- Stormwater Management – existing drainage would be maintained.

Whale's Tooth

Whale's Tooth Station would be located on Acushnet Avenue at the existing Whale's Tooth parking lot, which was constructed by the City of New Bedford in anticipation of the commuter rail project (Figure 3.2-31). The lot would be modified to include accessible spaces near the station platform, a pick-up/drop off area for buses and kiss & ride, and to provide better connections to Acushnet Avenue. The station would include intermodal connections, potentially including ferry services. The station would serve walk-in, bike-in, and drive-in customers. The Whale's Tooth Station design is summarized as follows:

- Parking Spaces – 748 total spaces consisting of 32 handicapped accessible and 716 standard spaces.
- Parking Lot Type – existing paved surface parking.
- Station Access Drive –driveway access off of Acushnet Avenue.
- Bus/Kiss & ride Accommodations – a 135-foot pick-up/drop-off area would accommodate up two 40-foot buses and provide a waiting area for kiss & ride. Wide aisles and adequate turning radii provide a bus route through the parking lot.
- Platform Type – one side platform.
- Platform Dimension – 800-foot high-level platform, 16 feet wide.
- Track Configuration – double track.

- Pedestrian Accommodations – ramps and stairs from the platform would be installed to connect with existing sidewalks adjacent to the existing parking facility.

- Feeder Bus – Pedestrian connections to the station would be improved and SRTA Routes 1, 3 and 11 would be extended.

- Stormwater Management – existing drainage would be maintained.

Dana Street (Whittenton Alternative)

Dana Street Station would be located just south of the Danforth Street grade crossing, within walking distance of downtown Taunton (Figure 3.2-32). The site is a currently vacant lot. The station would serve walk-in, bike-in, and drive-in customers. The Dana Street Station design is summarized as follows:

- Parking Spaces – 477 total spaces consisting of 9 handicapped accessible spaces and 468 standard spaces.

- Parking Lot Type – paved surface parking.

- Station Access Drive – driveway access from Dana Street.

- Bus/Kiss & ride Accommodations – a 110-foot pick-up/drop-off area would accommodate up two 40-foot buses and provide a waiting area for kiss & ride. Wide aisles and adequate turning radii provide a bus route through the parking lot.

- Platform Type – one side platform.

- Platform Dimension – 800-foot high-level platform, 12 feet wide.

- Track Configuration – double track.

- Pedestrian Accommodations – walkways would be provided that lead to the platform. Additional sidewalks would be constructed along Dana Street and Danforth Street, and future walkways could provide a continuous connection to downtown.

- Feeder Bus – GATRA Route 18 would be rerouted to provide access to the station.

- Stormwater Management – space has been reserved for a basin and drainage would tie into the municipal system.

South Station – All Rail Alternatives

The South Coast Rail alternatives would utilize future expanded operational capacity at South Station already being planned by MassDOT to fulfill existing and future needs independent of the South Coast Rail project; described in Section 3.2.3.3 as part of the No-Build Alternative.

The initial operational analyses conducted for the rail alternatives assumed expansion of South Station up to a capacity of fifteen tracks, which was the expansion considered reasonably foreseeable at that time. The operational analyses showed that the Stoughton and Whittenton Alternatives would be

operationally feasible. Without expansion of South Station the operational performance of these alternatives would suffer.

3.2.16 Layover Facilities

Both of the rail alternatives would require two overnight layover facilities, one on the Fall River Branch and one on the New Bedford Main Line. A midday layover facility would also be necessary near South Station in Boston. The overnight layovers would be necessary to store trains when they complete their evening runs and before morning service. The midday layover would be needed to store trains near South Station in between the AM and PM peak periods.

The overnight layover facilities ideally would be located close to the terminal stations at the end of the New Bedford Main Line and Fall River Secondary. If the layover facilities are near the termini, trains would not have to travel far to get to the start of their morning trips or from the end of their evening trips. If the layover facilities are distant from the termini, trains would need to make a long distance non-revenue (deadhead) movement before they start their morning trips or after they end their evening trips. The same logic is true for locating the midday layover facility as close to South Station as possible.

3.2.16.1 Overnight Layover Facilities

The DEIS/DEIR identified five alternative sites for overnight layover facilities. Church Street and Wamsutta sites were identified on the New Bedford Main Line, and the ISP Site, Weaver's Cove East, and Weaver's Cove West were identified on the Fall River Secondary. The DEIS/DEIR did not identify a preferred site on either branch. These sites were identified since they provide ample space for the layover facility program that includes:

- Six tracks approximately 950 feet long: five to store train sets and one track for maintenance equipment;
- 25-foot-wide roadway around the perimeter and between track pairs;
- Parking for approximately 40 cars including two handicapped spaces;
- Lighting for parking lot and between the tracks; and
- Storage building and electrical substation.

This program results in a need for a site that has a rectangular shape that is approximately 1,500 feet long and 180 feet wide.

Subsequent to the DEIS/DEIR, the alternative sites were reviewed and recommended sites identified on each branch, as documented in the February 2012 Layover Facility Site Selection (provided in Appendix 3.2-E). Drainage and stormwater management for these sites is described in the Chapter 4.17, *Water Resources*.

On the *New Bedford Main Line*, Wamsutta was considered the most favorable location to site a New Bedford layover facility as it has less environmental impact than the Church Street site from the perspective of land acquisition, tax revenue loss, wetlands, and hazardous materials. Wamsutta would also be operationally more efficient with its close proximity to the terminal station, saving the project roughly $500,000 annually.

On the *Fall River Secondary*, Weaver's Cove East was considered the most favorable location for a Fall River layover facility as it has the least environmental impacts of the Fall River sites with the fewest land acquisition requirements, wetland impacts, impacts to cultural resources and to wild and scenic rivers, and from the perspective of encountering hazardous materials. Weaver's Cove East would also be operationally more efficient than the ISP site with its close proximity to the terminal station, saving the project roughly $500,000 annually.

Wamsutta Site Overnight Layover Facility Site

This site is located on the east side of the right-of-way, opposite the proposed Whale's Tooth Station and adjacent to an existing CSX freight yard, near MP 54.7 (Figure 3.2-33). The Wamsutta site layover facility design is summarized as follows:

- Distance from Terminal – 0.3 mile south of Whale's Tooth Station
- Lead Track – single lead track
- Length of Yard – 1,200 feet
- Width of Yard – 200 feet
- Highway Access – 400-foot driveway to Wamsutta Street

Weaver's Cove East Overnight Layover Facility Site

This site is located on the east side of the right-of-way, opposite the formerly proposed Weaver's Cove LNG Site in Fall River, near MP 49.8 (Figure 3.2-34). The Weaver's Cove East site layover facility design is summarized as follows:

- Distance from Terminal – 1.5 miles north of Fall River Depot Station; 2.6 miles north of Battleship Cove Station
- Lead Track – single lead track
- Length of Yard – 1,050 feet
- Width of Yard – 200 feet
- Highway Access – 440-foot driveway to North Main Street

3.2.16.2 Midday Layover Facilities

The South Coast Rail would require midday storage in the Boston area. This is being investigated separately as part of the South Station Expansion Project, which has independent utility from the South Coast Rail project.

On April 19, 2013 the Secretary of Energy and Environmental Affairs issued the Certificate on the Environmental Notification Form (ENF) for the South Station Expansion project. The project also includes the construction of layover facilities at one or more sites within the greater Boston area. After completion of a layover facility alternative analysis that evaluated 28 potential locations, three sites for

new and/or expanded layover facilities were further considered as part of the ENF. These potential layover locations include:

- The Boston Transportation Department-owned Tow Lot located along Frontage Road approximately 1 track-mile from South Station;
- Beacon Yard Park a freight yard and intermodal terminal most recently used by CSX Transportation, Inc. (CSX) located along Cambridge Street in the Allston section of Boston, approximately 4 track-miles on the MBTA Framingham/Worcester Line from South Station;
- Readville Yard 2, an existing MBTA layover yard and maintenance facility located off Wolcott Court in the Hyde Park section of Boston) approximately 9 track-miles from South Station.

It was determined that no single remaining layover facility alternative has the physical space to fulfill the entire projected 2040 layover need, while layover of too many train sets approaching South Station from one location could cause conflicting railroad operations and create a bottleneck. The Secretary's Certificate requires MassDOT to evaluate a combination of the three recommended sites to assess how they can be integrated with the existing four layover sites serving South Station.

Should a midday layover solution in Boston not be available at the projected opening year of the South Coast Rail project, the projected operational performance for the rail alternatives may not be attainable, reducing the rail alternatives' ability to meet the project purpose and potentially affecting system-wide rail operational performance.

3.2.17 Property Acquisition

This section describes the property acquisition required for the rail alternatives. Property acquisition for the commuter rail alternatives includes land required for the construction of the railbed and track, bridges and culverts, rights-of-way, retaining walls, grade crossings, stations, layover facilities, and electrification of the alternatives.

For purposes of this discussion, "property acquisition" is defined as obtaining greater than a 500-square-foot portion, or a sliver of land more than 10 feet wide, of any parcel outside of the existing rights-of-way to accommodate permanent construction impacts, based upon conceptual engineering plans. Narrow slivers of parcels are not considered in the evaluation of property acquisition, given the scale and accuracy of the conceptual design. Temporary construction impacts beyond the limits of the existing rights-of-way would not require land acquisition (utilizing temporary construction easements instead) and are therefore not considered in this evaluation. Aerial photographs and public Massachusetts GIS information were examined in reference to preliminary engineering plans to identify encroachments onto adjacent parcels. Final engineering plans may show an increase or decrease of the actual area of acquisition required.

When evaluating each property acquisition, conceptual design plans (in CAD format) were compared with public GIS information. Where proposed construction required full-parcel acquisition, property size for each of these parcels was gathered from existing information contained at Assessors' offices in each municipality. The design endeavored to limit property impact to partial acquisitions wherever possible, unless partial-parcel acquisitions resulted in the remaining parcel being unusable to the existing owner. In these instances, the analysis accounts for full-parcel acquisitions. Where partial-parcel acquisition was required, property acquisition was calculated utilizing the public GIS information contrasting to

proposed limits of work at each function. Parcel acquisition needs would be re-evaluated during final design using more detailed property boundary data and refined right-of-way requirements mapping.

For new track right-of-way, layover facilities and electrification equipment, property acquisition has been limited to minimum footprints required to support each function (as described above) and related amenities. Related amenities include access roads for maintenance, stormwater management facilities, and employee parking areas where required.

Where property acquisition is required, the goal for MassDOT would be to reach agreements with existing owners for purchase of properties required by the project. However, the Eminent Domain process may be required. Once property has been acquired for the project, it is expected that the Commonwealth (or one of its assigns) would retain ownership of each parcel.

Property acquisition by alternative has been summarized in Table 3.2-20. Values in the table reflect both full and partial takings required for each alternative. Table 3.2-21 provides a summary of property acquisitions by layover facility.

Table 3.2-20 Summary of Property Acquisition by Alternative (Acres)

	Stations	Right of Way	Electrification	Total
Stoughton Electric	62.50	47.70	2.20	112.40
Stoughton Diesel	62.50	47.70	0.00	110.20
Whittenton Electric	54.80	55.50	2.20	112.50
Whittenton Diesel	54.80	55.50	0.00	110.30

Table 3.2-21 Summary of Property Acquisition by Layover Site (Acres)

Layover Facility	Total
Weaver’s Cove East Layover Facility (Fall River Secondary)	18.43
Wamsutta Layover Facility (New Bedford Main Line)	5.90

Chapter 4.2, *Land Use and Zoning*, provides a more detailed breakdown of property acquisition requirements of each alternative by municipality and project element.

3.2.18 Cost

This section summarizes the estimated capital costs for the rail alternatives presented as incremental funding needs over a 30-year period, a typical financing period. Capital equipment costs are presented as the incremental cost of the life of the equipment as defined by FTA guidelines. The net result of this analysis is the identification of the annual funding requirements above and beyond the costs already programmed for the horizon year (No-Build Alternative).

Capital costs include the cost of new infrastructure such as new track and stations, and cost of new transportation equipment, such as rail cars. The first step in developing the financial impact analysis is to convert the capital and operating cost estimates from base year (2012) dollars to the projected year-of-expenditure dollars.

The capital cost estimates for both infrastructure and equipment were escalated to year-of-expenditure based on current FTA criteria. These costs were then annualized based on the useful life of each element and a discount rate of 7 percent, in accordance with FTA guidelines.

Table 3.2-22 provides a summary of the cost estimate and analysis for the Stoughton Electric Alternative. The Whittenton Alternative would have a similar cost. Based on the cost estimates developed for the DEIS/DEIR, the cost of the diesel alternatives would be approximately 30 percent lower than the electric alternatives.

Table 3.2-22 Stoughton Electric Alternative Capital Cost

Item	
Total Infrastructure Cost	$1,090,568,000
Real Estate Cost	$ 52,430,000
Professional Services Cost	$ 147,767,000
Contingency	$ 345,700,000
Vehicle Cost	$ 180,970,000
Total	$1,817,435,000

Notes: Total infrastructure costs were estimated in 2012 dollars.
Professional services are 13.55 percent of infrastructure costs without contingency. Professional services include Design, Permitting, Construction Phase Inspection & Project Management.
Contingencies are 31.70 percent of infrastructure costs and include Indirect Soft Costs, Mitigation Contingency, and Construction Contingency.
Escalation was calculated at 3.25 percent per year per FTA criteria.

The Operations and Maintenance Cost (O&M) was calculated for the Stoughton Electric Alternative. The total amount in 2012 dollars is $ $33,914,000. The O&M cost for the Whittenton Electric Alternative would be $36,210,000 because of the longer length of track compared to the Stoughton Electric Alternative. Based on the O&M cost estimates developed for the DEIS/DEIR, the diesel alternatives would be approximately three percent lower than the electric alternatives.

3.2.19 Construction of the Rail Alternatives

This section describes the methodologies that would be used to construct the Stoughton or Whittenton Alternatives, including railbed and track, bridges and culverts, retaining walls, grade crossings, stations, layover facilities and electrification systems. The following sections describe the conceptual construction methodology. Detailed construction plans and sequencing would be developed in final design.

3.2.19.1 Track Construction—General Description

The proposed track work consists of construction of new track structure along existing active freight and passenger service areas as well as construction of new track along abandoned or new rights-of-way. The new track construction consists of single, double, and triple track sections and passing sidings, replacement of existing industry turnouts, and special track work. Common elements of the track construction include excavation, new track bed, ditches, ballast, concrete ties, and new steel rail. These improvements include the specific elements listed below.

- The existing ballast would either be undercut to remove silt, returning the existing ballast material to current specifications, or be removed and replaced by new ballast. Undercutting would clean the entire ballast section by lifting it into vibrating screens and returning the clean ballast to the rail bed, while silt would be wasted onto the shoulder or carried away. Regardless of which technique is utilized, at least 12 inches of clean ballast is required below the ties.

- The existing subballast would either remain in place with possible regrading or would be excavated and replaced with new material to meet current specifications.

- Ties would be completely replaced. It is anticipated that the entire line would be outfitted with concrete ties, elastomeric pads, and compression Pandrol rail clips.

- The existing jointed rail would be replaced with new 132 pound continuously welded rail.

- Existing embankments would be modified to accommodate the new track cross section, including (where appropriate) side drainage ditches, ballast side slopes, and retaining walls.

The methodology for the track construction for each segment is described in the following sections.

Track Construction on Active Rail Lines

Segments of the construction would occur on active track where service would need to be maintained during construction activities. The goal of the construction method for these segments is to minimize disruption to these services. Following is a summary of track segments with active track.

- **Northeast Corridor—**The NEC has passenger and freight service by Amtrak, the MBTA and CSX. The MBTA operates from 4 AM to 2 AM; Amtrak operates from 5 AM to 1 AM. Service operates seven days per week.

- **Stoughton Line—**The MBTA's Stoughton Line has commuter rail service from the existing Stoughton Station north to Canton Junction, where it connects to the NEC. The MBTA operates from 5 AM to 12 AM during weekdays only. MCRR has an active freight railroad operation that utilizes the MassDOT-owned Stoughton Line track through Taunton to the Dean Street area. MCRR operates on this section one to three days per week.

- **New Bedford Main Line—**CSX and MCRR have active freight railroad operations on the MassDOT owned New Bedford Main Line from New Bedford to Taunton where it connects to the Attleboro Secondary at Weir Junction. CSX currently operates along this line two days a week between Weir Junction and Cotley Junction and MCRR operates three days per week between Weir Junction and Whale's Tooth in New Bedford.

- **Fall River Secondary—**MCRR has an active freight railroad operation on the MassDOT owned Fall River Secondary from Fall River to where it connects to the New Bedford Main Line at Myricks Junction. MCRR currently operates on this line three days per week.

- **Attleboro Secondary—**CSX has an active freight railroad operation on the MassDOT owned Attleboro Secondary lines from Weir Junction to the NEC. CSX operates on this line five days per week.

The construction sequencing for the track construction would allow freight operations to be maintained throughout the majority of the track construction activities. Freight operations on the New Bedford Main Line and Fall River Secondary currently operate at a low frequency schedule. The construction activities would occur in small segments so the contractor can ensure that existing freight activities are maintained.

Certain segments of the existing Stoughton Line have active MBTA commuter rail and freight service that would need to be maintained during construction activities to construct a new second track. Construction would be similar to double track construction where freight lines currently operate.

However, due to the higher frequency of commuter rail service during the morning and evening peak periods (higher than the freight service), construction activities would be restricted during those times to minimize service impacts. It is assumed that freight deliveries can occur during the week and the corridor would be available for any construction activity for the entire weekend (Friday night through Monday morning), as there is currently no passenger service on the weekend. The following sections summarize the construction sequence.

Single Track Sections

In proposed single track sections, work must be staged to maintain passenger and freight traffic during the construction period. The general sequence of work in single-track sections would be as follows:

- Construct retaining walls and earthworks to the extent possible without affecting existing track.
- Construct bridges in the recommended phasing as outlined in Section 3.2.19.5, Construction of Bridges and Culverts, in order to maintain passenger and freight service.
- Install culverts while the track is temporarily out of service, both precast concrete box and pipe culverts. Many new culverts would be an extension of existing culvert structures.
- Construct new track in final position. Construction would be coordinated with passenger and freight service since existing track would be removed and existing ballast excavated in order to install the new track structure; temporary connections to existing tracks would be provided at limits of work segments.

Double/Triple Track Sections

In proposed double and triple track sections, the new track can be constructed without significantly disturbing the existing track, facilitating the construction of the new track structure while maintaining passenger and freight service on the existing track during construction. The existing track would be reconstructed after the new second track is constructed. The general sequence of work would be as follows:

- Construct retaining walls and earthworks to the extent possible without affecting existing track.
- Construct bridges in the recommended phasing as outlined in Section 3.2.19.5, Construction of Bridges and Culverts, in order to maintain passenger and freight service.
- Construct second track and third track (where proposed) in final position while maintaining passenger and freight operations on the existing track. The existing freight track may need to be realigned in some segments to allow space for construction of the new track structure on its proposed alignments.
- Construct turnouts at ends of double-track section. It is assumed that turnouts can be constructed while the track is out of service (i.e., overnight or during weekends).
- Shift passenger and freight service to completed second track.
- Construct remaining portions of abutments and bridges.

- Reconstruct first track in final position.

3.2.19.2 Track Construction – Stoughton Alternative

This section describes the track construction required for the inactive right-of-way of the existing Stoughton Line and the grade-separated crossing at Route 138.

Stoughton Line

The inactive Stoughton Line segment of the corridor is an existing railroad right of way that connects the Dean Street area in Taunton and the existing Stoughton Line at Stoughton Station. Construction can proceed unimpeded by active service. Construction would be similar to the single and double track construction as outlined in Section 3.2.19.1, subsection on Track Construction on Active Rail Lines.

Route 138 Crossing

The Route 138 crossing in Raynham is recommended for grade separation due to the high traffic volume on Route 138 and severe skew angle of the crossing. After analysis of several options, the preferred design would depress the railroad under Route 138. Since the profile of the railroad cannot exceed a 3 percent slope and the topography is very flat in this area, a boat section and retaining walls would be required for approximately 600 feet on either side of the underpass to depress the railroad into a cut section.

3.2.19.3 Track Construction—Whittenton Alternative

New track construction would be required on the inactive Whittenton Branch between Raynham Junction and Whittenton Junction. This segment of the corridor would be a new railroad on an abandoned right-of-way and would connect the Attleboro Secondary in Taunton to the Stoughton Line in Raynham. Construction can proceed unimpeded by active service. Construction would be similar to the single track construction as outlined in Section 3.2.19.1, subsection on Track Construction on Active Rail Lines.

3.2.19.4 Construction of Stations and Layover Facilities

Both rail alternatives include the construction of ten new stations and two new overnight layover facilities, as well as modifications to two existing stations. Work at Canton Center, Easton Village, Battleship Cove, King’s Highway, and Whale’s Tooth Stations would be predominantly platform construction. More substantial construction would be needed at Stoughton, North Easton, Raynham Park, Taunton (Stoughton Alternative), Dana Street (Whittenton Alternative), Taunton Depot, Freetown, and Fall River Depot Stations as well as the Weaver’s Cove East and Wamsutta layover facilities. The general sequence of work would be:

- Prepare the site including the placement of trailers, equipment, and supplies;
- Place erosion and sedimentation controls;
- Begin earthwork including construction of water quality management structures;
- Relocate existing utilities and place new utilities;
- Survey land and layout the site;

- Construct buildings, platforms, pedestrian overpasses, sidewalks, roadways, and parking lot;
- Construct tracks as described in Section 3.2.19.1, Track Construction;
- Construct catenary structures and signal systems; and
- Clean up the site.

3.2.19.5 Construction of Bridges and Culverts

Many of the existing undergrade (railroad) bridges along the New Bedford Main Line, Fall River Secondary, Attleboro Secondary, and Stoughton Line do not meet current design standards for commuter rail service. In order to accommodate the requirements for the commuter rail alternatives, the bridges would be rehabilitated or replaced as described in Section 3.2.11, Bridges and Culverts. Since the majority of the existing freight and passenger service must be maintained during construction activities, the proposed undergrade bridge improvements would be constructed and staged to allow the passage of trains while they are under construction. The construction staging strategy is especially important where bridges are over environmental resource areas like rivers and wetlands to minimize impacts to these resources.

In some cases, the overhead (highway) bridges would need to be reconstructed to increase the railroad vertical or horizontal clearance under the bridge. However, if existing vertical and horizontal clearances are sufficient, overhead bridges would not be modified.

For all undergrade bridges, the majority of the work area would be limited to the area behind the existing abutments. Only during erection of the superstructure would work be done over existing roadways or waterways. This phase of construction must be coordinated with local and state officials and would follow an accepted traffic management plan for bridges over roadways.

For bridges over waterways, the contractor would ensure that all construction is performed within the temporary and permanent impact limits set forth by the environmental permits. Any dewatering, if required, would also be performed in accordance with the environmental conditions. No debris would be allowed to enter the watercourse. For longer spans over watercourses, particularly the Taunton River, it may be necessary for the work to be done using barges. The three Taunton River bridges on the Stoughton Line and the Cedar Swamp River bridge on the Fall River Secondary would be constructed while the tracks are out of service or during temporary track shutdowns since constructing temporary bridges would have a significant impact on the environmental resources at these locations.

For construction in areas where the track is active, the construction must be properly phased so that service is not interrupted. In order to maintain service, support of excavation and of the track may be necessary. All work would be coordinated with the railroad and accepted prior to construction. For all bridges, any demolition materials would be removed from the site and properly disposed of off-site. For construction of the three Taunton River bridges on the Stoughton Line, it is assumed that the existing track would be taken out of service for a period to construct the new bridges to minimize impacts to the river.

Construction sequencing is an important consideration at railroad bridges where active rail must be maintained. For track segments without active rail service, or with rail service which can be deactivated, construction on undergrade bridges can proceed unimpeded. At locations where rail service must be

kept active, bridge staging would generally be similar to one of the schemes described below depending on the number of tracks the existing structure can accommodate and the number of tracks being proposed over the crossing. Structural staging may be affected by track staging along the alignment, staging requirements of nearby structures, and property or wetland boundaries. For more details on construction staging of the bridges, refer to the Construction Staging Memorandum, included as Appendix 3.2-F.

For culverts that would remain in place, the existing culverts would be extended to accommodate the wider rail bed. The culvert extensions would be installed before the slope embankment is modified for the new track structure. At each location, the inlet could be sand bagged to temporarily stop the flow of water and pumps can be used to divert the flow for construction of the culvert end base of gravel and stone in the dry. The pipe extensions would be fitted to the existing culverts and stone pads installed to minimize erosion at the culvert ends.

For construction of new culverts to replace existing culverts, the typical sequence of construction would be to excavate above the slab and behind the abutment walls of the existing culvert. The inlet could be sand bagged to stop the flow of water and pumps can be used while constructing the new gravel and stone foundation in the dry. After the foundations are constructed a precast concrete box culvert and cast-in-place headwalls can be installed. For more details on construction staging of the culverts, including a list of culverts, refer to the Construction Staging Memorandum, included as Appendix 3.2-F.

3.2.19.6 Construction of Grade Crossings

Grade crossing improvements would be constructed with construction work zones that may require temporary travel lane closures and/or lane width reductions. The majority of the work would be performed while maintaining vehicular and rail traffic during construction activities. Existing grade crossing equipment would be removed and new equipment installed in place. A list of grade crossings can be found in the Construction Staging Memorandum, Appendix 3.2-F.

3.2.19.7 Construction of Electrification Systems

Construction for the electric commuter rail alternatives includes constructing a new electrification system and connecting to the existing electrification system on the NEC at Canton Junction. Diesel alternatives would not require this infrastructure. Section 3.2.14 of this chapter describes the proposed electrification system.

New electrification infrastructure would be required for the electric commuter rail alternatives south of where the route diverges from the NEC in Canton.

The new electrification infrastructure would include traction power facilities and an OCS as well as modification to the signal system to make it compatible with electrified rail service. Since operations would utilize part of the electrified NEC, the project would use a similar system.

The traction power system providing power to the OCS is made of three different types of traction power facilities: Traction Power Substation, Switching Station, and Paralleling Station.

The Stoughton and Whittenton Alternatives electrification system would consist of two main substations, two switching stations, and six paralleling stations.

Each traction power facility would include:

- Switchgear
- Transformers (main traction power and autotransformers)
- Protection relaying & controls
- Disconnect switches (structure mounted)
- Auxiliary transformers and power systems
- Grounding and Bonding System
- SCADA Equipment

The traction power substation is the largest type of facility and requires a high voltage (115 kV) utility power interface to provide power to the rest of the system. Switching stations and paralleling stations are smaller facilities that do not require a high voltage utility supply.

The traction power facilities would be adjacent to the existing right-of-way, so construction could be staged with little or no impacts to the existing train service. Typically, the construction of each site would proceed independently early in the overall construction process. The main substations are more complex and construction would be started as early as possible. Once construction is complete, each substation would be tested and energized prior to completion of the OCS and other systems.

The OCS consists of concrete foundations, steel poles, contact wire, feeder wire, static wires and sectionalizing switches. It is largely dependent on the track installation. Therefore, the OCS would typically be installed after the track is in place. OCS pole foundations are set with respect to the center of the track. Poles are typically placed a minimum of 10 feet from the track centerline, which is within the track right-of-way. Pole footings would be installed using off track equipment during times when no train service is operating to minimize impact to existing operations. In areas where access along the right-of-way is limited, excavation for the foundations would be completed by on-track equipment. This would have more impact on rail operations, especially in single track areas, and may be restricted to nights or weekends. Precast foundations could be used to reduce the installation time. In areas where there is no existing service, construction could proceed more quickly, as construction would not be restricted by operations.

After the foundations are in place, the catenary poles would be erected. Pole mounted steel work (cantilevers, drop tubes, disconnect switches, etc.) would then be installed. With the steel and poles in place, the OCS conductors would be strung, tensioned and anchored, hangers installed, clipped in place and registered. This work would all be done during foul time or track out-of-service using on or off track, space permitting. Once a section is complete, cable connections, wire terminations, and jumpers would be installed.

The system would not be energized until all signal and communications systems were fully installed and operational, to ensure that all remote monitoring and control facilities were working correctly.

The wayside power system requirements are set with respect to the track alignment and location of equipment at interlockings. Therefore, the wayside power cubicles, required to remotely control and

operate the OCS sectionalizing switches and control interlocking lighting, would be installed at the same time as the OCS.

3.2.20 Ridership

In order to estimate future ridership projections for the South Coast Rail alternatives in greater detail, the Central Transportation Planning Staff (CTPS) refined their regional travel demand model set to include regional transportation projects, land use alternatives based on regional plans for the study area, and the proposed operation plans for the alternatives.

The ridership analysis of the DEIS/DEIR was updated for the FEIS/FEIR using an updated version of the CTPS travel demand model. The analysis took into account the results of the 2010 Census, changes to the No-Build condition projects, and changed the analysis year from 2030 to 2035.

3.2.20.1 Model Basis

The CTPS model used a modeling process consistent with those of other major transportation projects in eastern Massachusetts. This travel demand model was refined specifically for the South Coast Rail study area, utilizing the current Boston region MPO travel model and the statewide model for the south coast rail study area. The model set that CTPS uses for forecasting travel demand is based on procedures and data that have evolved over many years and incorporated assumptions based on accepted practice, professional judgment and policy decisions relating to items such as model method, service plans and demographic assumptions. This modeling method allowed for a consistent comparison of the alternatives based on their projected ridership. The CTPS regional model and its underlying assumptions are subject to review and approval by FHWA and FTA because the model is used to develop the regional emissions estimates used for transportation conformity determinations on the long-range transportation plan and transportation improvement program.

The basis for the CTPS model is summarized below, with supporting technical information provided in Appendix 3.2-G. (prepared in 2009). Updates to the CTPS model incorporated for the FEIS/FEIR analyses are discussed in Appendix 3.2-H.

Existing Transit Modes

Connectivity to other transit modes provides a larger coverage area for the project while it increases mobility and regional opportunity. The model includes all of the major transit modes, such as commuter rail lines, the subway system (including both light and heavy rail lines), ferry service, and bus routes in regional communities. The model allows for transfers between all of these modes. Access to the transit system is allowed via walk/bike, transit, park-and-ride, and kiss-and-ride modes.

Regional Plan

The demographic forecasts were created by the local Regional Planning Agencies (RPAs) in the model area such as the Southeastern Regional Planning and Economic Development District (SRPEDD), Old Colony Planning Council (OCPC), and Metropolitan Area Planning Council (MAPC) for use in their most recently adopted Regional Transportation Plan (RTP). The land use assumptions do not include the possible casino developments. The transportation improvements included in this study are those highway improvement projects most likely to be built by 2035 and are included in the last federally approved and fiscally constrained Regional Transportation Plans in the model area. This includes the

major transit projects assumed in the State Implementation Plan (SIP) and included in the Boston Region RTP, such as:

- Green Line Extension Project
- Fitchburg commuter rail improvements
- Assembly Square, Orange Line Station
- Fairmont commuter rail station improvements
- 1,000 additional parking spaces throughout the commuter rail system

Other transportation projects assumed in the analysis are based on the SRPEDD and the OCPC Regional Transportation Plan Highway Improvements Projects.

Ridership forecasts were developed for all alternatives for the 2035 forecast year. For the No-Build (Enhanced Bus) Alternative, the ridership model assumes enhancements to the existing commuter bus service. For the Build Alternatives, the ridership model assumed that the transportation network would be updated to reflect the project improvements and the model was re-run for the various options. The outputs of these model runs were compared to the No-Build Alternative to see what changes in travel patterns would occur to the transportation system due to the South Coast Rail alternatives.

Population and Employment Densities

To establish where people are coming from and going to, the travel demand / ridership model takes into account the population and employment densities of the region. This is the basis for an origin/destination summary that ultimately translates into the number of people who would use the rail or bus alternatives. The model also accounts for the proximity of population densities to establish how the riders access the stations. Knowing whether riders walk, bike, drive or take the bus, for instance, is also relevant to ensure that the stations are properly designed with adequate sidewalks, bike storage capacity, parking capacity, and good connections to other transit modes.

3.2.20.2 Ridership Model Inputs

The travel demand model relies on the following elements and assumptions to estimate future ridership projections:

- Operating Plan
- Station Locations
- Station Parking, Availability and Cost
- Fares

These elements are discussed below.

Operating Plan

The operating plan for the travel demand model was developed using minimum acceptable service assumptions based on the MBTA Service Delivery Policy. Rail travel times for the Stoughton/Whittenton Alternatives, which include dwell times at the stations, were calculated for the 2035 operation and reflect future improvements and service modifications to the rail corridors.

The operating plan includes 30 minute peak period peak direction service along the Fall River Secondary and New Bedford Mainline. Peak period peak direction headways would be approximately 18 minutes on the portion of the alignment north of Myricks Junction.

Station Locations

How well a transit alternative appeals to potential riders is directly related to how easily patrons can get to a station. The travel demand model, therefore, takes into account the surrounding transportation infrastructure and any barriers that make access to the station difficult, which could potentially add to the in-vehicle travel time to the stations.

Station Parking, Availability and Cost

In order to plan for and design station parking that accommodates future demand, the majority of proposed stations were modeled as if there were no constraints on the amount of available parking. Running the model unconstrained at the proposed stations ensures that the true attractiveness of a station would be reflected in the total number of riders who would be expected to use the new service. This applies to the riders who would arrive to the station by car. All other modes (i.e. patrons arriving to the station by walking or riding a bicycle) would be unaffected by the parking supply. Stations that do not offer parking were modeled without parking. Parking constraints were applied at Taunton station where the desire to accommodate future transit-oriented development (TOD) was a driving factor. Stations where TOD is projected would limit the parking supply to the benefit of greater development intensity in the immediate vicinity of the station to encourage future transit riders to live and work within walking distance of the station.

Fares

The model also considers the economics of using the proposed transit system. This allows the model to weigh the economic attractiveness of riding the proposed system compared to the economics of continuing to drive or using the existing commuter bus service. Fares for the No-Build Alternative were based on the existing commuter bus monthly fare structure; fares for the Build Alternatives including both the rail and bus alternatives were based on the current MBTA commuter rail monthly fare structure.

3.2.20.3 Ridership Modeling Results

Overview

For the purpose of portraying the ways in which the South Coast Rail project shifts and adds new ridership, the results presented are new transit trips at the proposed South Coast Rail project stations, new linked-trips, new system-wide trips and the total reduction in vehicle miles travelled (VMT).

A summary of new station boardings pertains to the new South Coast Rail stations only and gauges the overall benefit to the region provided by each alternative.

The total number of linked trips per alternative represents the shift in mode choice due to a South Coast Rail project alternative. For instance, for mode of access, residents of the South Coast communities currently have few options outside driving to work. With the South Coast Rail project, people would have regional transit opportunity, which was previously not available, giving South Coast residents an additional mode by which they could get to work. The additional transit choice presented by the project would increase the number of people who would choose to take transit to work. This number is represented in the linked trips increase and represents the number of people who, without the project, would have otherwise driven to work.

New system-wide boardings represent the overall draw to the commuter rail transit system due to the South Coast Rail project, which represents an increase in capacity along other commuter rail lines as a particular alternative attracts system-wide new ridership. This total is also used to calculate overall cost-effectiveness of the project.

The VMT measure quantifies how many miles of auto travel would be removed from the region due to the project. As people switch from driving to using the new transit project, the reduction in VMT correlates to air quality benefits due to the project.

The CTPS modeling for the FEIS/FEIR included updated demographic data for 2035 and newer information on future year background transportation projects that are consistent with the Long Range Transportation Plans (LRTP) of the Metropolitan Planning Organizations (MPOs) in the study area.

The base year, No-Build, Stoughton Electric and Whittenton Electric Alternatives were assessed using the CTPS regional travel demand model. The Stoughton and Whittenton Diesel Alternatives were examined using an elasticity based method that took into account the electric variant modeling results and the effect of the slower travel time of the diesel alternatives compared to the electric alternatives. Elasticities were used since the diesel operating plans mirrored those of the electric options, except for travel time. It is an accepted practice in the transportation planning profession to use elasticities when only one service plan variable changes, such as travel time.

The No-Build assumes land use changes and the transportation projects included in the LRTP, and existing private bus service from New Bedford, Fall River, and Taunton into Boston. The No-Build also improves the frequency of the private bus operations serving the South Coast rail Study area.

The performance metrics examined, include linked and unlinked transit trips by mode, station boardings in the study area and VMT.

Ridership

An overview of changes in ridership among the alternatives conducted for the DEIS/DEIR and the FEIS/FEIR is presented in Table 3.2-23. The FEIS/FEIR results differ from the DEIS/DEIR in several ways. The base year was updated from 2006 to 2010. The forecast year was extended out to from 2030 in the DEIR to 2035 in the FEIS/FEIR. The list of transportation projects in the LRTP is also significantly different. The DEIS/DEIR included the Urban Ring Phase II, the Silver Line Phase III connection, and a host of other projects that are not included in the most current fiscally constrained LRTP. The land use is another important change. The 2030 forecasts were developed with an eye towards a lot of population growth in the suburbs and employment growth in the major cities, like Boston and Taunton in the study area. Given the current economic climate, the 2035 forecasts have been scaled back in absolute numbers, along with a more targeted smart growth approach. The FEIS/FEIR service plans for the Stoughton

Electric and Whittenton Alternatives also differ slightly from those used in the DEIS/DEIR, being more refined and the FEIS/FEIR now includes a feeder bus network that complements the proposed stations.

Table 3.2-23 Ridership of Alternatives (DEIS/DEIR and FEIS/FEIR)

	DEIS Stoughton Electric	FEIS Stoughton Electric	DEIS Whittenton Electric	FEIS Whittenton Electric
Battleship Cove	210	240	200	200
Downtown Taunton/Dana Street	n/a	n/a	890	320
Easton Village	320	150	320	150
Fall River Depot	740	840	640	750
Freetown	240	180	160	160
King's Highway	460	520	390	480
North Easton	750	460	750	490
Raynham Park	550	430	600	520
Taunton	510	670	n/a	n/a
Taunton Depot	410	400	360	360
Whale's Tooth	600	680	510	610
Total Station Inbound Boardings	4,790	4,570	4,820	4,040
Total Reduction in VMT (compared to No-Build (Enhanced Bus))	295,900	-255,932	228,000	-201,232

All of these changes led to demand estimates in the FEIS/FEIR that are between 10 and 20 percent lower for the Build Alternatives than were estimated in the DEIS/DEIR. The most significant change is the land use assumed in 2035, which drives the trip making from population locations (South Coast Rail Study area) to employment centers, namely Boston and Cambridge. The change in station location from Downtown Taunton to Dana Street also substantially reduced ridership of the Whittenton Electric Alternative compared to the DEIS/DEIR.

Transit Metrics

The four key transit metrics presented in Table 3.2-24 consist of daily linked transit trips, daily unlinked trips, boardings on the commuter rail system, and boardings on the private buses serving the study area compared to the True No-Build scenario. Detailed breakdowns of the system-wide transit results are included in Appendix 3.2-H.

The transit system grows from 1.27 million unlinked transit trips in 2010 to 1.61 million in 2035 if there are no improvements to the transportation system other than what was included in the LRTP. The growth in unlinked transit trips is primarily due to demographics, but some transit improvements such as the Green Line Extension, Assembly Square Orange Line Station, and the new Fairmount Line Stations are adding to the increase in transit trips in the future.

The enhanced bus service under the No-Build Alternative represents a slight improvement of the private bus system and this adds 2,210 unlinked transit trips to the system daily. The Stoughton Electric option adds 7,100 unlinked transit trips compared to the No-Build/Enhanced Bus, while the Whittenton Electric option adds 6,000 unlinked trips.

Table 3.2-24 2035 Regional Transit Modeling Results (Daily)

Year / Scenario	2010 Existing Conditions	2035 True No-Build	2035 No-Build / Enhanced Bus	2035 Stoughton Electric	2035 Whittenton Electric	2035 Stoughton Diesel	2035 Whittenton Diesel
Unlinked Transit Trips	1,270,700	1,612,000	1,614,210	1,621,310	1,620,210	1,621,010	1,620,010
Difference with No-Build/Enhanced Bus	na	-2,210	na	7,100	6,000	6,800	5,800
Linked Transit Trip	1,018,000	1,294,400	1,296,300	1,301,800	1,301,000	1,301,500	1,300,650
Difference with No-Build/Enhanced Bus	na	-1,900	na	5,500	4,700	5,200	4,350
Commuter Rail (1)	145,000	178,200	177,710	188,010	187,110	187,460	186,660
Difference with No-Build/Enhanced Bus	na	490	na	10,300	9,400	9,750	8,950
Study Area Private Buses (2)	1,600	4,100	6,000	1,100	1,200	1,250	1,350
Difference with No-Build/Enhanced Bus	na	-1,900	na	-4,900	-4,800	-4,750	-4,650

(1) Commuter system calibrated to conductors counts

(2) Study area means the South Coast Rail project study area

There are two reasons the Whittenton Electric option has less demand than the Stoughton Electric option:

- The service plan for the Whittenton Electric option has slower travel times from the southernmost stations to South Station than the Stoughton Electric option.
- The Whittenton Electric option has a different stop pattern in Taunton, which causes the additional travel time.

The diesel options for the Stoughton and Whittenton Alternatives have slower travel times into Boston from New Bedford, Fall River, and Taunton, resulting in less demand relative to their electric options. The Stoughton Diesel option has 6,800 more unlinked trips than the No-Build, 300 less than the electric option. The Whittenton Diesel option has 5,800 more unlinked trips than the No-Build, 200 less than the electric option.

The daily system wide linked transit trips grows from 1.02 million 2010 to 1.29 million in the 2035 No-Build scenario. The enhanced bus service to the No-Build Alternative provides a small improvement, adding 1,900 daily linked transit trips.

The Stoughton Electric adds 5,500 more linked transit trips and the Whittenton Electric option adds 4,700 daily linked transit trips relative to the No-Build/Enhanced Bus Alternative. The Stoughton Diesel option has 5,200 new linked transit trips and the Whittenton Diesel option 4,350 new linked transit trips relative to the No-Build. The reasons for these differences are the same as for the unlinked transit trips described above.

The No-Build/Enhanced Bus Alternative causes a decrease in commuter rail boardings, by 490. This option adds bus service in the study area, which siphons off commuter rail riders from the Providence, Stoughton, and Middleborough commuter rail lines. The Stoughton Electric option adds 10,300 boardings daily to the commuter rail system and the Whittenton Electric option adds 9,400 boardings daily to the commuter rail system relative to the No-Build/Enhanced Bus. The Stoughton Diesel option adds 9,750 boardings and the Whittenton Diesel option adds 8,950 boardings relative to the No-Build. This is between 450 and 550 lower than their corresponding electric options.

The private bus system in the study area had 1,600 daily boardings in 2010, but is forecasted to grow to 4,100 in 2035 without any service improvements (primarily due to population and employment growth and demographic trends increasing transit usage). The No-Build/Enhanced Bus Alternative improves the private bus service in the South Coast rail corridor by adding frequency and this increases ridership to 6,000, an increase of 1,900 boardings. The Stoughton Electric option has 1,100 and the Whittenton Electric option 1,200 private bus trips relative to the No-Build/Enhanced Bus. The Stoughton Diesel option has 1,250 private bus trips and the Whittenton Diesel option 1,350 new private bus trips relative to the No-Build/Enhanced Bus. This is about 150 boardings more than the corresponding electric options.

Conclusion

The results of this analysis show that the Stoughton and Whittenton Electric options both capture a significant number of trips, between 4,700 and 5,500, respectively, on a daily basis in 2035 relative to the No-Build/Enhanced Bus scenario that would have otherwise been made by auto. This translates into a VMT savings, Vehicle Hours Traveled (VHT) reduction, and emissions benefits, which are discussed in

Chapter 4.9, *Air Quality*.[16] The major difference between the two commuter rail alternatives are travel times for trains traveling the outer stations, south of Taunton, into Boston. The longer travel times from New Bedford and Fall River up through Taunton in the Whittenton Electric option reduces demand at these stations.

The stations in Taunton also see a reduction in the Whittenton Electric option, but drive access demand increases at Raynham Park Station, due to people willing to bypass the slower segment of train travel and pick up the line north of the delay during the AM time inbound commute. These results show the same pattern as observed in the DEIR for the electric options, although they are showing less demand. This is primarily a function of the most current RPA adopted land use assumptions in the model area and represents a more conservative view of future smart growth strategy consistent with the South Coast Rail Corridor Plan.

In general, the electric options attract more riders than the diesel options due to the faster travel times, which is a function of faster acceleration of the electric technology being used by the locomotives.

However, regardless of the technology, electric or diesel, the Stoughton Alternative consistently attracts more riders than the Whittenton Alternative especially for trips south of Taunton, where additional travel time is needed to traverse the Whittenton Junction. The travel time difference between the Stoughton and Whittenton Alternatives is a more significant factor in attracting riders than the travel time differences associated with the technology, diesel versus electric.

3.3 EVALUATION OF FEIS/FEIR ALTERNATIVES

This section provides an overview of the performance of the alternatives with regard to achievement of the project purpose, their practicability and their environmental impacts, in particular with regard to aquatic resources. The following alternatives are analyzed in this FEIS/FEIR:

- No-Build (Enhanced Bus) Alternative
- Stoughton Electric Alternative
- Stoughton Diesel Alternative
- Whittenton Electric Alternative
- Whittenton Diesel Alternative

The characteristics of the above alternatives are described in Section 3.2. The analysis of their impacts in detail is presented in Chapter 4. Chapter 7 provides a summary of the mitigation commitments incorporated into the project.

This section summarizes and compares the characteristics of the Build Alternatives analyzed in this FEIS/FEIR and is a continuation of the alternatives screening process that began prior to the DEIS/DEIR. The discussion includes a set of evaluation criteria that are consistent with the evaluation criteria utilized in the earlier stages of alternatives screening, but more refined in consideration of the more

[16] The air quality analysis shows that the technology drives the benefits. Electric technology provides substantially more emissions savings than the diesel options and the TSM alternative when the transit vehicle emissions are combined with the passenger vehicle emissions being saved.

detailed level of information available and taking into consideration the comments on the DEIS/DEIR. Specific screening criteria were refined from the earlier stages of the alternatives analysis based on operational and environmental issues. The earlier analysis criteria were expanded with subcriteria to include a more detailed evaluation of how well the alternatives would meet the project purpose, whether or not they are practicable to construct and operate, and the magnitude of their environmental impacts and/or benefits.

The results of the evaluation process are used to reach a conclusion regarding the least environmentally damaging practicable alternative (LEDPA) for the South Coast Rail project. As explained in Section 3.3.4, USACE has concluded the Stoughton Electric Alternative is the LEDPA and has identified the Stoughton Electric Alternative as the preferred alternative under NEPA.

3.3.1 Project Purpose

This section evaluates the alternatives that advanced to the FEIR/FEIS with regard to the overall project purpose "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts to enhance regional mobility. The following aspects were considered in the evaluation. The Build Alternatives were compared against the No-Build Alternative as well as with each other.

- Ridership demand – This aspect relates to meeting the demand for public transportation.
- Improve quality of service – This aspect evaluates how well each alternative provides a transit trip that is competitive to travel by car and meets MBTA's Service Delivery Policy.
- Reduce vehicle miles traveled – This aspect evaluates to which extent each alternative provides public transit connections between New Bedford/Fall River and Boston that offers the opportunity to shift from auto mode reliance to using the transit mode.
- Improve regional mobility – This aspect evaluates the extent to which each alternative provides public transit connections between New Bedford/Fall River and Boston and provides public transit connections between South Coast cities (New Bedford, Fall River, Taunton and others).

3.3.1.1 Ridership Demand

The Build Alternatives are predicted to result in 3,930 to 4,570 daily boardings at the new stations (see Table 3.3-1). Private bus service boardings under the Build Alternatives would decline substantially to 1,100 to 1,350 (compared to 6,000 in the 2035 No-Build condition) as a result of the diversion of passengers to the new rail options. When the rail ridership and remaining bus ridership are considered together, the Build Alternatives would meet 65.5 to 71.0 percent of the demand for approximately 8,000 work trips from the South Coast region to Boston.

Due to a faster travel time to Boston, the Stoughton Alternatives achieve greater ridership in the Southern Triangle than the Whittenton Alternatives. For example, the Stoughton Electric would have 840 daily boardings at Fall River Depot compared to 750 under the Whittenton Electric Alternative.

The Whittenton Alternatives ridership is also less than the Stoughton Alternatives because the Whittenton alignment does not include the Taunton Station, which has 670 daily boardings under the Stoughton Electric Alternative. The Whittenton Alternative station closest to downtown Taunton (Dana

Street) has substantially lower ridership (320 daily boardings under the electric alternative). The Whittenton Electric Alternative boardings at Raynham Park (520) would be higher than under the Stoughton Electric (430). This is because under the Whittenton Alternative, the Raynham Park Station would be more convenient to some commuters than would Dana Street; however, under the Stoughton Alternative, the Taunton (Dean Street) station would in theory be more convenient to those same commuters than would Raynham Park.

Table 3.3-1 Daily Ridership Demand by Alternative (2035)

Name	New Rail Station Boardings[2]	Boardings at Existing Commuter Bus Services	Total Service to South Coast Region	Percentage of Met Ridership Demand [1]
No-Build (Enhanced Bus) Alternative	na	6,000[3]	6,000	75.0%[3]
Stoughton Electric Alternative	4,570	1,100	5,670	70.9%
Stoughton Diesel Alternative	4,430	1,250	5,680	71.0%
Whittenton Electric Alternative	4,040	1,200	5,240	65.5%
Whittenton Diesel Alternative	3,930	1,350	5,280	66.0%

1 Total Service to South Coast region divided by the number of daily work trips from the South Coast region to Boston (approximately 8,000)

2 Relocated Stoughton Station not considered "new" for purposes of calculating new boardings

3 This is an artifact of the model; whether such private bus service would actually occur is uncertain. Future private bus operations would be far less attractive due to increased travel time but because travel time would still be better than by car and there would be no alternative it would absorb the demand in the model.

The difference in ridership between the electric and diesel versions of the alternatives is small, with the diesel alternative rail ridership at new stations being approximately three percent lower than the corresponding electric alternative due to slightly longer travel times. Despite having lower rail ridership, the Stoughton Diesel Alternative has the highest total service to the South Coast Region when considered together with bus service (although the difference from the electric version is negligible—10 boardings).

Travel Time

Since New Bedford/Fall River commuters currently rely on cars and private bus services, an improved quality of service would provide a comparable or competitive travel time and improved reliability with respect to existing commuter options during peak commuting periods. The average commuting time by car during rush hour is currently 90 minutes. The CTPS travel demand model projects slower commutes as congestion along already slow corridors continues to increase. A future (2035) commute from New Bedford and Fall River to Boston is expected to be approximately 10 to 30 minutes longer than in 2009 (in the peak period).

Travel time for the rail alternatives was based on operational analyses, which identified the segments of the rail corridors that would operate at top speed as well as segments where speed is constrained due to speed restrictions, geometry, vehicles, power mode, dwell times and number of stations and civil restrictions. Each commuter rail alternative has two overall run times: one for electric locomotives and one for diesel locomotives, as maximum speeds under the electric alternatives are greater than under diesel alternatives.

The Stoughton Electric Alternative achieves the fastest travel times (77 minutes between New Bedford and Boston during the peak period). The Stoughton Diesel Alternative takes approximately 5 minutes

longer than the electric alternative to travel the same route because of the additional time diesel locomotives need to accelerate from the stations. Travel times are presented in Table 3.3-2.

Table 3.3-2 Average Travel Times by Alternative (New Bedford to South Station Peak Period)

Name	Travel Time (min)
No-Build (Enhanced Bus) Alternative	100
Stoughton Electric Alternative	77
Stoughton Diesel Alternative	82
Whittenton Electric Alternative	84
Whittenton Diesel Alternative	89

The longer route of the Whittenton Electric Alternative results in a total travel time approximately seven minutes longer than the Stoughton Electric Alternative (84 minutes compared to 77 minutes). The Whittenton Diesel Alternative takes 5 minutes longer to travel from New Bedford to Boston than the Whittenton Electric Alternative and has the longest travel time of the rail alternatives.

Service Delivery Policy

While an alternative might offer benefits for the transit system in the South Coast region, it may be an unattractive service for the communities it is designed to serve because it offers too few trips. In order to maintain acceptable service, the MBTA has established a Service Delivery Policy[17] to ensure it provides quality transit services that meet the needs of the riding public. The minimum frequency of service levels provides the guidelines by which the MBTA maintains accessibility to the transportation network within a reasonable waiting period. The minimum frequency of service standards is the minimum frequency that must be maintained in a service. Commuter Rail and Commuter Bus minimum frequencies should provide 3 trips in a peak direction during the AM and PM peak periods.[18]

The Stoughton and Whittenton Alternatives (electric and diesel variants) would all meet the minimum service delivery policy standard. The No-Build Alternative would not meet this standard.

3.3.1.2 Vehicle Miles Traveled

VMT is an important gauge for an alternative's transportation system benefits. VMT measures the extent of motor vehicle operation or the total number of vehicle miles traveled within the study area on given day. This particular measure quantifies how many miles of travel would be removed from the regional roadway network by commuters who elect to travel by train or bus rather than drive. This reduction in driving has several environmental benefits, notably, cleaner air and a reduction in greenhouse gas emissions. Fewer cars on the road also eases congestion along highway corridors.

Table 3.3-4 summarizes the daily reduction in VMT provided by each alternative based on updated CTPS projections for 2035 (Appendix 3.2-H).

The Stoughton Electric Alternative achieves the greatest reduction in daily VMT of all the alternatives, approximately 54,700 VMT per day greater than the Whittenton Electric Alternative. The Stoughton Diesel Alternative has the second greatest VMT reduction, approximately 6.5 percent less than the

[17] Massachusetts Bay Transportation Authority, Service Delivery Policy, MBTA Board of Directors approved January 14, 2009.
[18] Between LIRR, MNRR, MBTA, and METRA, the average service provided is 2.9 peak period trains.

Stoughton Electric Alternative. With the longest travel time and lowest ridership, the Whittenton Diesel Alternative is also the least effective of the rail alternatives in reducing regional VMT, although it still provides substantial benefits (reduction of 186,306 VMT per day).

Table 3.3-4 Regional VMT Reductions by Alternative (2035, Auto and Bus Transit)

Alternative	VMT Reduction (daily miles)
No-Build (Enhanced Bus) Alternative	0
Stoughton Electric Alternative	-255,932
Stoughton Diesel Alternative	-240,348
Whittenton Electric Alternative	-201,232
Whittenton Diesel Alternative	-186,306

1 Reduction in VMTs provided by an alternative divided by the maximum reduction of VMTs (in this case, Stoughton Electric with roughly 255,932 fewer vehicle miles traveled per day)

3.3.1.3 Regional Mobility

This section discusses the number of interregional links provided by each alternative consistent with the goal of the project to improve regional mobility. An interregional link is a link that provides a one-seat ride from one municipality to another. The Stoughton and Whittenton Alternatives generate similar benefits with regard to interregional mobility and each provides 41 interregional links. The No-Build Alternative retains existing regional mobility but does not provide many of the interregional links provided by the Build Alternatives, nor does it provide a direct link between any of the communities served by the Build Alternatives and Boston.

Table 3.3-5 highlights the interregional links provided by the Stoughton and Whittenton Alternatives.

Table 3.3-5 Interregional Links – Stoughton and Whittenton Alternatives[1]

	Boston	Westwood	Canton	Stoughton	Easton	Raynham	Taunton	Freetown	Fall River	New Bedford
Boston		X	X	X	X	X	X	X	X	X
Westwood	X		X	X	X	X	X	X	X	X

Fall River	X	X	X	X	X	X	X	X		
New Bedford	X	X	X	X	X	X	X			

1 Inter-municipal connections not included.

3.3.1.4 Summary

The No-Build (Enhanced Bus) Alternative does not meet the project purpose and need nor its goals and objectives. All Build Alternatives meet the purpose and need. Among them the Stoughton Electric Alternative best meets the project's goals and objectives as reflected in the aspects discussed above.

The Stoughton Diesel Alternative and the Whittenton Electric Alternative follow closely behind, generally performing well in meeting the goals and objectives, although to a lesser degree than the Stoughton Electric Alternative. The Whittenton Diesel Alternative performs the worst relative to the other Build Alternatives.

3.3.2 Practicability

This section describes the practicability of construction or operation for each of the proposed alternatives analyzed in this FEIS/FEIR.

Section 3.3.1 documented how each of the Build Alternatives meets the project purpose. The discussion below provides data on how practicable each of the alternatives would be to implement based on the Permit 404 definition of practicable: "capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purpose." Four sub-criteria were used to evaluate how practicable the alternatives are:

- Cost per Rider– Measures how costly it would be to provide an alternative compared to the number of riders expected to use the system.
- Construction Schedule – The time required to construct each alternative is also a measure of practicability because longer construction schedules become increasingly more expensive, as well as delay the delivery of project benefits.
- On-Time Performance – Measures how well the alternatives would be able to serve the South Coast Region in terms of providing the passengers an assurance that they will arrive on time and measures how capacity constraints translate into impacts on the overall MBTA commuter rail system.

3.3.2.1 Cost Per Rider

This criterion evaluated how well an alternative performs based on how a balance of capital and operating and maintenance cost to the benefit of the service, or the number of riders projected to use the system. The metric for this criterion is cost per rider, which includes infrastructure construction, land acquisition, environmental mitigation, brownfield site remediation and other construction elements based on the more refined preliminary engineering design as well as the cost of operating and maintaining the system. A breakdown of capital cost and operation and maintenance cost estimates can be found in Section 3.2.18.

Table 3.3-6 compares the cost per rider of each alternative based on the cost estimates and the 2035 CTPS ridership projections. The Stoughton Diesel Alternative would have the lowest cost per rider, at $29.71. The Stoughton Diesel and Stoughton Electric Alternatives are more cost effective than the corresponding Whittenton Alternatives, due to the higher annual maintenance cost associated with the longer track length and lower ridership under the Whittenton Alternatives. The diesel variants of the alternatives are more cost effective than the electric variants for both the Stoughton and Whittenton

corridors because of lower capital and operating costs. It was assumed the capital cost of the diesel alternatives would be 30 percent less than the electric alternatives and operating and maintenance costs would be 3 percent less.

Table 3.3-6 Cost per Rider by Alternative

Name	Cost per Rider [1]
Stoughton Electric	\$35.28
Stoughton Diesel	\$29.71
Whittenton Electric	\$39.60
Whittenton Diesel	\$33.32

1 Annualized capital cost (over 30 years) and annual operating and maintenance cost estimates divided by 2035 annual commuter rail system passengers. CTPS daily ridership annualized assuming 260 weekdays per year.

3.3.2.2 Construction Schedule

The time required for construction affects the length of short-term impacts and the startup date for new transit services. Alternatives were evaluated to determine whether each alternative could be constructed within a reasonable, four-year, timeframe in order to achieve the project. A 4-year construction schedule has been outlined in Governor Patrick's *South Coast Rail, A Plan for Action*. In addition to trying to maintain this schedule, a shortened construction period would ensure lower construction costs. Construction costs, which typically escalate over time, would increase significantly with longer construction periods (particularly with regard to the cost of materials such as steel and concrete).

Construction schedules were established based on construction sequencing outlined in Section 3.2. Construction of track, bridges, culverts, grade crossings, electrification and whether the construction would occur along active or inactive corridors, among other components, all contribute to the construction duration required. Table 3.3-7 compares the construction schedules of the alternatives.

Table 3.3-7 Construction Schedule by Alternative

Name	Construction Schedule (years)
No-Build	0.0
Stoughton Electric	4.5
Stoughton Diesel	4.0
Whittenton Electric	4.5
Whittenton Diesel	4.0

1 Construction schedule of an alternative divided by the minimum construction time (in this case, Stoughton and Whittenton Diesel which could be constructed in 4.0 years)

All Build Alternatives would have an approximate construction schedule of 4 to 4.5 years, which is considered within an acceptable range.

3.3.2.3 On-Time Performance

While project travel time is an important initial criterion in evaluating the practicability of an alternative (as was done during the initial evaluation phases), the reliability of meeting that travel time on a

consistent basis (as expressed by on-time performance) is another key factor to consider. Infrastructure constraints in particular can affect on-time performance and an alternative's reliability. "On time" is defined as being no more than 5 minutes late, particularly for routes with published schedules such as a commuter rail or commuter bus service and for which this particular metric, the system on-time performance is evaluated. While on-time performance of one commuter rail or bus route is an important measure, the on-time performance of a combined system more accurately measures how well both a particular alternative will perform and how well it will do so without impacting the commuter system as a whole. As a point of reference, the MBTA System Wide Commuter Rail On-Time Performance for calendar year 2008 ranged from 78 to 95 percent. The on-time performance of each alternative is summarized in Table 3.3-8.

Table 3.3-8 On-Time Performance by Alternative

Name	On-Time Performance [1]
Stoughton Electric Alternative	97.9%
Stoughton Diesel Alternative	95.9%
Whittenton Electric Alternative	97.9%
Whittenton Diesel Alternative	95.9%

1 On-time performance for south side terminals as a result of the alternative's operating plan. On-time performance based on Systra's Network Simulation Analysis of Proposed 2030 MBTA/Amtrak Operations

As shown in Table 3.3-8, all Build Alternatives achieve an acceptable on-time performance.

3.3.2.4 Practicability Summary

The Corps has determined that the Stoughton and Whittenton Alternatives (electric and diesel) are both practicable alternatives.

3.3.3 Beneficial Effects and Environmental Impacts

This section compares each alternative's beneficial and adverse impacts to the aquatic, natural and human environment, and was undertaken in a manner compatible with the Corps' *Highway Methodology*[19] to evaluate alternatives and ensure that a transportation agency's preferred alternative is consistent with federal wetlands regulations, including 30 CFR 320-334 and 40 CFR 230 *et seq*.

The discussion below identifies beneficial or adverse impacts to the aquatic, natural and human environment to occur as a result of each alternative, particularly to wetlands, ACECs, threatened and endangered species, protected open space, public water supplies, land use, noise, air quality and environmental justice communities. These resources were selected from a full range of environmental impacts criteria because they are principal categories that either must be considered for permits and approvals and/or resulted in the greatest magnitude of change between all of the alternatives.

As stated in the Guidelines at Title 40 of the Code of Federal Regulations 230.10(a), "no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences." Therefore, the discussion below identifies impacts to the aquatic environment under the Clean Water Act, but also identifies other impacts to the

[19] United States Army Corps of Engineers. NEDEP-360-1-30, The Highway Methodology Workbook. October 1993.

overall natural environment (including the human environment), as is required under the Guidelines. The specific measures for each aspect are listed below.

The environmental impacts evaluation was based on two factors: "What are the beneficial effects and what are the adverse impacts?" These factors were further specified and evaluated based on their relevance to the project purpose, relationship to applicable statutes and regulations and the extent to which they would be likely to differ among alternatives:

- Beneficial Effects
    - To what extent would an alternative improve transportation conditions?
    - How well does an alternative serve environmental justice populations?
    - What are the air quality benefits that would be provided by each alternative?
    - What are the benefits that would be provided by each alternative to reduce greenhouse gas emissions that contribute to global climate change?
    - What smart growth opportunities would be provided by each alternative?
- Adverse Impacts
    - What would be the permanent wetland loss (in acres; edge and interior wetlands and floodplains)?
    - What would be the number of acres of protected open space[20] that would be directly impacted, acres of land acquisition and municipal tax loss?
    - What would be the number of acres of protected public water supply lands (active and inactive Mapped Wellhead Zone 1) that would be directly impacted?
    - What would be the noise impacts of each alternative?
    - What would be the number of acres of mapped Priority Habitat (state-listed rare species) that would be lost (edge and interior habitat)?

In addition to the aspects above, all other environmental aspects analyzed in Chapter 4 and 5 were also taken into consideration in evaluating the impacts and beneficial effects of the alternatives. Section 3.3.3.1 identifies the beneficial environmental effects of each alternative. Section 3.3.3.2 compares the alternatives based on key environmental impact criteria.

3.3.3.1 Beneficial Effects

This section focuses on the environmental benefits of each alternative by summarizing the benefits that would be provided to the transportation system, environmental justice populations, air quality, climate change, and smart growth. Environmental Justice and smart growth were evaluated qualitatively. Air quality and climate change were evaluated quantitatively.

Transportation

Public Transportation

The Build Alternatives would provide new public transportation service between the South Coast region and Boston with up to 4,570 daily boardings at new rail stations plus 1,100 boardings on existing bus

[20] Protected public open space lands are protected under Massachusetts' State Constitution, Article 97 (parks, conservation lands, recreation areas, wildlife refuges) and Section 4(f) of the Department of Transportation Act.

services or approximately 71.0 percent of the demand of 8,000 daily (i.e., weekday) work trips from the South Coast region to Boston.

The Stoughton Electric Alternative would result in the greatest beneficial effect, with the largest number of people benefitting from this new service (4,570 daily riders compared to 4,040 for Whittenton Electric) originating from the South Coast communities such as Fall River and New Bedford, which currently have the longest commute to Boston without public transportation. The Whittenton Alternative would benefit fewer people and a relatively smaller number of people would originate from the South Coast communities. Because the Whittenton Alternative would have relatively fewer riders from the municipalities that are the most distant from Boston, it would also result in a smaller decrease in daily VMT compared to the No-Build/Enhanced Bus Alternative than the Stoughton Alternative (201,232 vs. 255,932) and thus less benefits to the transportation system.

All Build Alternatives would provide a highly reliable public transportation service.

Regional Transportation Connectivity

The Stoughton and Whittenton Alternatives would have similar beneficial effects in terms of providing a one-seat ride from one municipality to another; so called interregional links.

Regional Freeway Conditions

The Build Alternatives would result in similar benefits to the regional freeway system. The four freeway segments analyzed on Route 24 between I-495 and I-93/Route 128 would see an improvement in Level of Service (LOS) under the Build Alternatives, including during the morning peak hour for all four segments (LOS E to LOS D or better; further information on these designations is provided in Chapter 4, [Section 4.1: Transportation]). The two segments of Route 24 south of I-93 and south of Pond Street would experience similar improvement in the southbound direction in the evening peak hour. Because of these changes, all Route 24 freeway segments from I-495 to I-93 under the Build Alternatives would operate at LOS D or better. There would also be improvements on I-93. I-93 south of Furnace Brook Parkway would also improve in the northbound direction in the morning peak hour (from LOS F to LOS E or better) and the two segments of I-93 south of Furnace Brook Parkway and south of Route 3 would improve (from LOS E to LOS D or better). Under the Build Alternatives, the two segments of Route 140 that were analyzed would continue to operate at LOS C or better.

Environmental Justice

This section compares the alternatives with regard to disproportionate adverse impacts and benefits to environmental justice populations, including property acquisition, change in noise or vibration levels or air quality, and the presence of traditional cultural properties and open space, improved access to transit services making it easier to reach employment and educational opportunities, general mobility, and improved air quality.

No-Build (Enhanced Bus) Alternative

Although there would be a minor improvement in the quality of transit service under the No-Build Alternative, the benefits resulting from improved transit access under the Build Alternatives would not occur.

Build Alternatives

Benefits associated with the Build Alternatives would be available to all populations regardless of designation. Increased access would reduce travel times to Boston and other employment centers. Average travel time savings from Fall River, Taunton, and New Bedford greatest under the Stoughton Electric Alternative, followed by the Whittenton Alternative which would improve travel times by 14 percent. The Stoughton Electric also represents the greatest travel time savings to colleges and hospitals. The Whittenton Diesel Alternative typically represents the least travel time savings of the rail alternatives.

The beneficial effects (Table 3.3-9) to environmental justice populations that would result from the South Coast Rail project vary considerably by alternative and community. Property values in environmental justice neighborhoods near stations may increase as a result of improved access to transit and subsequent TOD. If property values get too high, environmental justice populations may be priced out of their current locations. Conversely, property values in environmental justice neighborhoods along the alternative alignments may decrease as a result of increased noise from train operations.

Table 3.3-9 Summary of Beneficial Effects on Environmental Justice Populations

	Stoughton Electric	Stoughton Diesel	Whittenton Electric	Whittenton Diesel
Beneficial Effects (percent improvement compared to No-Build Alternative)				
Access to Jobs-[2]				
Taunton	118	77	67	44
Fall River	187	151	140	113
New Bedford	21	4	-1	-2
Access to Colleges[3]	78	46	52	33
Access to Hospitals[3]	188	135	132	102
Travel Time to Boston[4]	47	32	33	23
Station Area TOD[5]	Yes	Yes	Yes	Yes

1 Business and job displacements would result from private property acquisition for the Mansfield and Fall River Depot Stations, and would be minor as compared to the overall workforce in the surrounding community. See Chapter 4.2, *Land Use*, and Chapter 4.3, *Socioeconomics*.
2 Provided as an average in improvement, as compared to the No-Build Alternative, in access to basic, service, and retail jobs within a 90-minute radius of each municipality. Source: CTPS 2009.
3 Provided as an average in improvement, as compared to the No-Build Alternative, in access from Taunton, Fall River, and New Bedford to colleges and hospitals. Source: CTPS 2009.
4 Provided as an average in improvement, as compared to the No-Build Alternative, in travel times from Taunton, Fall River, and New Bedford to Boston's South Station. Source: CTPS 2009.
5 Qualitative assessment of the potential for transit-oriented development in the vicinity of the station site that would benefit environmental justice populations. Source: Goody Clancy

The Stoughton Electric Alternative would provide the greatest improvement in access to jobs for both Fall River and New Bedford environmental justice populations (187 and 21 percent, respectively).

Air Quality

This section compares the impacts of the alternatives on air quality. This includes a mesoscale analysis which estimates the area wide emissions in 2035 of VOCs, NO_X, CO_2, CO, and PM emissions based upon changes in the average daily traffic volumes, roadway lengths, and vehicle emission rates (including trains).

This section also compares the alternatives at the microscale level by assessing the potential for impact of motor vehicles and train locomotives on typically congested intersections ("hotspot locations") around stations, added the emissions of the diesel commuter rail trains to the intersection receptor locations to calculate the highest concentrations of CO, PM_{10}, and $PM_{2.5}$.

Greenhouse Gas (GHG) emissions were compared for the alternatives with regard to motor vehicle and train locomotive GHG emissions. The stations and layover facilities will all be open to the outside and will not need heating/air conditioning equipment. Because no buildings are associated with any of the alternatives, no discussion and consideration of recommendations of the Massachusetts Zero New Energy Building Task Force was included.

The air quality study qualitatively evaluated the potential for impact due to air toxics, as required in the Secretary of Environmental Affairs Certificate on the ENF. Most air toxics originate from human-made sources, including on-road mobile sources, non-road mobile sources (e.g., airplanes), area sources (e.g., dry cleaners) and stationary sources (e.g., factories or refineries).

Table 3.3-10 presents the mesoscale analysis results for all the alternatives.

No-Build Alternative

The No-Build Alternative would consist of enhancing current bus service along existing roads and highways. The limited increase in bus service along the roadways would have a minimal effect on the air quality within the study area.

Mesoscale Results—The No-Build Alternative VOC and NO_X emissions are typically lower than the Existing Conditions emissions due to the implementation of state and federal emission control programs, such as the Federal Motor Vehicle Emission Control Program, the Stage II Vapor Recovery System, and the Massachusetts Inspection and Maintenance program.

Microscale Results—The No-Build Alternative will meet the National Ambient Air Quality Standards (NAAQS) for CO, PM10, and PM2.5, and will not cause any new violation of the NAAQS; increase the frequency or severity of any existing violations; or delay attainment of any NAAQS.

Build Alternatives

Mesoscale Results—All rail alternatives would reduce emissions of $NO_{X,}$, CO, and CO_2, in comparison to the No-Build Alternative (See Table 3.3-10). All of the rail alternatives have a negligible effect on particulate matter emissions. The electric alternatives all have lower in emissions than the corresponding diesel alternative for all of the pollutants. The difference between the diesel and electric is most notable with the NO_X emissions where the emissions for the electric alternative are substantially less than the corresponding diesel alternative. This is due to the higher NO_X output related to the locomotives burning diesel fuel. The Stoughton Electric Alternative generally results in the greatest reduction in emissions which is consistent with the estimated highest reduction in VMT for the Stoughton Electric Alternative.

Table 3.3-10 Summary of the 2035 Mesoscale (Regional) Air Quality Analysis for the South Coast Rail Alternatives

		Vehicle Miles Traveled (VMT)[1]	Volatile Organic Compound (VOC) (kg/day)	Oxides of Nitrogen (NO_x) (kg/day)	Particulate Matter 10 (PM_{10}) (kg/day)	Particulate Matter 2.5 ($PM_{2.5}$) (kg/day)	Carbon Monoxide (CO- Winter) (kg/day)	Carbon Dioxide (CO_2) (tons/year)
No-Build	Total	118,897,192	22,200	19,256	3,240	1,490	1,050,356	24,717,339
Stoughton Electric	Total	118,641,260	22,160	19,159	3,240	1,490	1,048,074	24,656,479
	Difference from No-Build	-255,932	-40	-98	0	0	-2,281	-60,859
Stoughton Diesel	Total	118,656,844	22,160	19,210	3,241	1,491	1,048,400	24,688,173
	Difference from No-Build	-240,348	-40	-46	1	1	-1,956	-29,166
Whittenton Electric	Total	118,695,960	22,170	19,169	3,240	1,490	1,048,554	24,667,849
	Difference from No-Build	-201,232	-30	-88	0	0	-1,801	-49,490
Whittenton Diesel	Total	118,710,886	22,170	19,227	3,241	1,491	1,048,908	24,703,175
	Difference from No-Build	-186,306	-30	-29	1	1	-1,448	-14,164

1 VMT represents the vehicle miles traveled on an average weekday in 2035.
2 The Build Alternatives used for the air quality analysis include the physical and operational mitigation proposed to improve traffic operations (as outlined in Chapter 4.1, *Transportation*).
Note: Includes transit-related emissions changes (bus and rail)

Microscale Results—The trains that will be used on the rail alternatives could be electric or diesel. The electric trains do not emit air pollutants and will not have any contribution to air quality impacts on receptor locations around the stations. All of the pollutant concentrations are below (in compliance with) the NAAQS. The rail alternatives will not substantially change any of the concentrations of CO, PM_{10}, and $PM_{2.5}$. All of the increases are less than 1ppm for CO and less than 0.3 $\mu g/m^3$ for PM_{10} and $PM_{2.5}$ and all Build Alternatives will meet NAAQS for CO, PM10, and PM2.5, nor will they cause any new violation of the NAAQS; increase the frequency or severity of any existing violations; or delay attainment of any NAAQS.

Contribution to Climate Change/Greenhouse Gas Emissions

Climate change is an important consideration in evaluating the South Coast Rail project alternatives. The primary greenhouse gas emitted by transportation sources is CO_2. This analysis looked at CO_2 emitted by locomotives as well as reduction from reduced VMT (see Table 3.3-10).

No-Build Alternative

The No-Build Alternative would not reduce VMT and would thus not decrease GHG emissions.

Build Alternatives

The reduction in GHG emissions is directly related to the reduction in VMT. The Build Alternatives achieve the reduction in VMT by shifting commuters from cars to commuter rail. The Stoughton Electric Alternative would result in the greatest reduction in GHG emissions (60,859 tons/year of CO2), a greater reduction than the Whittenton Electric Alternative which would reduce GHG emissions by 49,490 tons/year. Overall the diesel alternatives would result in less reduction of GHG compared to the electric alternatives for both the Stoughton and Whittenton Alternatives.

Smart Growth

Each Build Alternative is anticipated to induce additional growth within the South Coast region as a result of improved transit access. However, the induced growth from each is relatively small (3.7 percent) in comparison to the No-Build Alternative, which is projected to increase the number of households by 75,212 by 2035. Local effects would vary considerably, especially in communities with stations. However, the cumulative impact even at the local level would be minimal. From a regional perspective the differences between the alternatives are minimal; cumulative effects are not a differentiator. As compared to the No-Build Alternative, the economic trends in combination with the impacts from both Build Alternatives would beneficially contribute to economic growth in the South Coast region. Under scenario 1 a wide range of local impacts would be broadly distributed, whereas under Scenario 2 these impacts are expected to be more concentrated in Priority Development Areas (PDAs).

As stated in the *South Coast Rail Economic Development and Land Use Corridor Plan,*[21] commuter rail service to the South Coast will generate nearly $500 million in new economic activity every year. This is new growth by the year 2030 that would not occur without the new infrastructure. The rail connection is projected to create between 3,500 and 3,800 net new jobs within the Commonwealth by 2030—about

[21] Massachusetts Executive Office of Transportation and Massachusetts Executive Office of Housing and Economic Development. *South Coast Rail Economic Development and Land Use Corridor Plan*. June 2009.

two-thirds of which would locate in the South Coast region with the remaining third in Boston-Cambridge and other communities outside the region.

The Corridor Plan would be implemented by MassDOT throughout the 31-community region regardless of which alternative was selected, so there would be no substantive difference among alternatives with regard to the majority of smart growth benefits. These benefits include protecting the Priority Preservation Areas (PPAs), and concentrating development in the PDAs. The principal differences among the alternatives would be with regard to their ability to promote concentrated development (transit-oriented development) at station areas. Transit-oriented development (or redevelopment), as illustrated by the concepts included in the Corridor Plan report, would include mixed high-density residential, retail, and commercial/office development at certain station locations. The benefits of this transit-oriented development would be to increase local tax revenues; decrease VMT, and decrease Greenhouse Gas emissions. As outlined in the Corridor Plan, transit-oriented development would be likely as new development or re-development at the Downtown Taunton, Taunton, Freetown, Fall River Depot, King's Highway, Whale's Tooth, Easton Village, and Raynham Place stations.

In summary, the increases in population and jobs from induced growth are expected to increase economic activity and property tax revenues within the South Coast region. The Build Alternatives would support the TOD and smart growth strategies outlined in the Corridor Plan.

3.3.3.2 Adverse Impacts

The following sections compare the alternatives based on five adverse environmental impacts:

- The amount of permanent wetland loss (in acres) (edge and interior wetlands and floodplains) and wetland loss in ACECs.
- The number of acres of protected open space that would be directly impacted, acres of land acquisition and municipal tax loss. Protected public open space lands are protected under Massachusetts' State Constitution, Article 97 (parks, conservation lands, recreation areas, wildlife refuges) and Section 4(f) of the Department of Transportation Act.
- The number of acres of protected public water supply lands (active and inactive Mapped Wellhead Zone 1) that would be directly impacted.
- The amount of noise impacts.
- The number of acres of mapped Priority Habitat (state-listed rare species) that would be lost (edge and interior habitat).

In addition to the above, other, related impacts are also disclosed, including:

- Secondary and/or Indirect Wetland Impacts
- Biodiversity Impacts, including wildlife habitat fragmentation.

Permanent Direct Wetland Loss

Impacts to waters of the United States, including adjacent wetlands, are the principal category of environmental impacts that must be considered by the Corps for Clean Water Act Section 404 permits

and by the Massachusetts Department Environmental Protection for variances under the Massachusetts Wetlands Protection Act (WPA). Direct wetland impacts, both temporary and permanent, are anticipated for each of the proposed alternatives.

Temporary impacts include short term disturbances (erosion controls, temporary structures, etc.) to wetlands and waterways during construction that would cease once construction activities are complete.

Permanent impacts are those that would result in the loss of waters of the United States, including wetlands. Permanent impacts may include, but are not limited to, wetland fill, dredging, and watercourse relocation or alteration. This analysis also evaluated the amount of wetland fill within an ACEC, as wetlands within ACECs receive a higher level of state regulatory protection.

No-Build (Enhanced Bus) Alternative

No wetland impacts would occur under the No-Build Alternative.

Stoughton Electric Alternative

The Stoughton Electric Alternative would impact 12.3 acres of waters of the United States—1.9 acres of open water and 10.4 acres of vegetated wetlands (primarily forested wetlands).

In terms of state wetland resources, Stoughton Electric Alternative would permanently impact 16,813 linear feet of Bank, 9.6 acres of Bordering Vegetated Wetland (BVW), 6.7 acres of Bordering Land Subject to Flooding (BLSF), and 7.9 acres of new development Riverfront Area. The largest impacts would occur in Raynham (1.3 acres of BVW) and Stoughton (2.0 acres of BVW), particularly south of the former Greyhound Park where the corridor forms the border of the Hockomock Swamp and then crosses through Pine Swamp. These impacts would occur in and along the edge of the abandoned railroad embankment. Minor impacts would occur along the components of the Southern Triangle, along the remainder of the Stoughton Line north of the Hockomock Swamp, at the Canton, East Taunton, Easton Village, and Raynham Park stations, and at traction power stations Stoughton TPSS-2 in New Bedford, Stoughton PS-1 in Easton, and Stoughton SWS-1 in Canton. Impacts would be closely evaluated during final design and would be minimized or avoided to the maximum extent practicable. Potential permanent wetland impacts along the Stoughton Line include 0.2 acre within the Hockomock Swamp ACEC. Indirect impacts within the Hockomock swamp would be minimal due to the existing rail bed and the proposed elevated trestle that would span 1.6 miles of the Hockomock Swamp. The elevated trestle would facilitate free wildlife passage across the proposed route, as well as maintain the current hydrology of the area. Additionally, approximately 1.5 acres of ORWs would be impacted along the Stoughton Electric Alternative.

Stoughton Diesel Alternative

Impacts to wetlands for the Stoughton Diesel Alternative are similar to the impacts identified above for the Stoughton Electric Alternative. The diesel alternative does not require traction power substations and would result in approximately 0.01 acre of permanent wetland impacts less than the Stoughton Electric Alternative along the New Bedford Main Line.

Whittenton Electric Alternative

The Whittenton Electric Alternative would impact 11.2 acres of waters of the United States—1.8 acres of open water and 9.4 acres of vegetated wetlands (primarily forested wetlands).

In terms of state wetland resources, the Whittenton Electric Alternative would permanently impact 16,581 linear feet of Bank, 8.4 acres of BVW, 5.0 acres of BLSF, and 7.8 acres of new development Riverfront Area. By town, the largest amount of impacts would occur in Berkley (1.4 acres of BVW) and Stoughton (2.0 acres).This alternative would leave the Stoughton Line corridor at Raynham Junction and instead would follow the Whittenton Branch to the Attleboro Secondary. This diversion would avoid wetland impacts in Pine Swamp. As with the Stoughton Alternative, the majority of impacts would occur in and along the edge of the abandoned railroad embankments. Minor impacts would occur along the components of the Southern Triangle, along the remainder of the Stoughton Line north of the Hockomock Swamp, at the Canton, East Taunton, Easton Village, and Raynham Park stations, and at traction power stations Whittenton TPSS-2 in New Bedford, Whittenton PS-1 in Easton, and Whittenton SWS-1 in Canton. Impacts would be avoided or minimized during final design to the maximum extent practicable.

Potential permanent wetland impacts along the Stoughton Line segment of this alternative include 0.2 acre within the Hockomock Swamp ACEC. Indirect impacts within the Hockomock swamp would be minimal due to the existing rail bed and the proposed elevated trestle that would span 1.6 miles of the Hockomock swamp. The elevated trestle would facilitate free wildlife passage across the proposed route, as well as maintain the current hydrology of the area. Additionally, approximately 1.1 acres of ORWs would be impacted along the Whittenton Electric Alternative.

Whittenton Diesel Alternative

Impacts to wetlands for the Whittenton Diesel Alternative are similar to the impacts identified above for the Whittenton Electric Alternative. The diesel alternative does not require traction power substations and would result in approximately 0.01 acre of permanent wetland impacts less than the Whittenton Electric Alternative along the New Bedford Main Line.

Secondary and/or Indirect Wetland Impacts

The secondary and/or indirect impact analysis evaluated the effects of the alternatives on wetland functions and values for all wetlands within 100 feet of the project limits (see Section 4.16.7.2). These impacts cannot be quantified, but are presented in a qualitative approach that identifies, for each wetland, the principal functions and values provided by that wetland, the magnitude of impact to those functions based on the physical extent of the impacts in comparison to the overall size of the wetland.

The results of the analysis are summarized in Table 3.3-11 and described below.

No-Build Alternative

The No-Build Alternative would not have any secondary and/or indirect impacts.

Table 3.3-11 Secondary and/or Indirect Effects on Wetlands within 100 feet of the Rail Segments along the Stoughton/Whittenton Alternative[1,4,5]

Function	Total Wetlands[2]	Negligible/ Minor		Moderate/ High		Total
		Active	Out-of-Service	Active	Out-of-Service	
Groundwater recharge/discharge	339/333	0	0/3	0	0/1	10/14[3]
Floodflow alteration	112/122	33	18/17	9	8	68/72
Fish and shellfish habitat	84/78	16	15/11	0	0	32/35
Sediment/toxicant/pathogen retention	145/151	45	11/8	20	5/2	88/88
Nutrient removal/retention/transformation	145/152	45	11/8	20	5/2	87/87
Production export	206/203	38	23/14	11	10/7	86/86
Sediment/shoreline stabilization	203/204	8	2/0	0	5	19/19
Wildlife habitat	144/145	39/40	52/50	13	12/10	118/127
Recreation	52/49	4	10/7	0	0	14/14
Educational/scientific value	10	0	5	0	0	5/5
Uniqueness/heritage	9/8	0	0	0	0	0/0
Visual quality/aesthetics	77/73	33	25/22	6	0	64/67
Endangered species habitat	96/102	27	15/12	4	22	68/69

1 Includes all wetlands within 100 feet of the right-of-way
2 Wetlands that perform each function as a principal function
3 Includes wetlands that would receive stormwater discharge that are more than 100 feet from the right-of-way
4 Where the alternatives are identical only one value is shown
5 The No-Build Alternative would have no indirect/secondary effects on wetlands

Build Alternatives

For both the Stoughton and the Whittenton Alternatives the majority of wetlands along either the active or inactive segments of the Stoughton Alternative would experience negligible to minor impacts to functions and values. In most cases, the wetlands are relatively large in comparison to the area in which functions would be lost or altered, and there would be little overall effect on the ability of the wetland to provide these functions. For both alternatives the wetland functions most affected would be wildlife habitat.

Although wetlands along both the active and inactive segments would experience a decrease in their ability to support wildlife habitat functions, including rare species habitat, these changes would be greater in the inactive segments due to the barrier effect of the reconstructed tracks. For both alternatives, the segment through the Hockomock Swamp would result in a minor effect on wildlife habitat through creation of a canopy gap although there would be no barrier to wildlife movement.

Stoughton Electric Alternative—The Stoughton Electric Alternative would affect the habitat function of 116 of the 144 wetlands, with 77 percent of the affected wetland experiencing negligible or minor impacts (see Table 3.3-11). The overhead catenary system would affect 58 wetlands as a result of the overhead catenary structures required to provide electric rail service, a majority of the wetlands which provide visual or aesthetic value.

Stoughton Diesel Alternative—The Stoughton Diesel Alternative would affect the habitat function of wetlands to the same degree as the Stoughton Electric Alternative with the exception of the effects to the 58 wetlands as a result of the catenary system.

Whittenton Electric Alternative—The Whittenton Electric Alternative would affect the habitat function of 113 of the 145 wetlands, with 80 percent of the affected wetland experiencing negligible or minor impacts (see Table 3.3-11). The overhead catenary system would affect 52 wetlands as a result of the overhead catenary structures required to provide electric rail service, a majority of which provide visual or aesthetic value.

Whittenton Branch—Along the Whittenton Branch, overall indirect or secondary impacts to wetlands are generally small, due to the proportionately small direct impacts along the route. A large portion of one wetland, Wetland TWB-08.1, would be eliminated to construct the railroad. This is a disturbed, mainly unvegetated wetland that has developed within the right of way due to compression of soils from ATV and other use of the path, and provides little function or value. The remaining impacts to wetlands along the Whittenton Branch are negligible or minor. The most affected wetland function is wildlife habitat, as barrier and noise effects along the currently inactive right of way could impact existing habitat or reduce the effective contiguous habitat size of wetlands. This effect is most likely to be seen in the approximately 0.3 mile section of the Whittenton Branch where the right of way branches off from the stone quarry access road. In this section, in the vicinity of Wetlands TWB 03.1 through TWB 01, both the western and eastern sides of the tracks have large areas of undeveloped land with only a narrow, mostly-vegetated path between them, whose size may be effectively reduced by constructing the railroad.

In summary, the effects of the Build Alternatives would be similar. The No-Build Alternative would not have any secondary and/or indirect impacts.

Open Space

This section discusses direct impacts to public open space (parks, conservation lands, recreation lands, and wildlife refuges), which are protected under Article 97 of the Massachusetts Constitution, and to publicly-owned wildlife sanctuaries and refuges which are considered "special aquatic sites" under the federal 404(b)(1) Clean Water Act Guidelines. Although the South Coast Rail project is currently not undergoing review by a federal transportation agency, this criterion also includes those properties protected under Section 4(f) of the federal Department of Transportation Act because the FTA and FHWA are cooperating agencies under NEPA.

No-Build (Enhanced Bus) Alternative

Minor increases in existing bus service along existing major roadways would have no impact on open space resources.

Build Alternatives

Table 3.3-12 provides a comparison of the ACEC land acquisition requirements for each South Coast Rail alternative. The Stoughton and Whittenton Electric Alternatives would each require acquisition of the same small portion (0.5 acre) of conservation land in the Hockomock Swamp ACEC. The parcel would be used for traction power substation for the Stoughton or Whittenton Electric Alternatives. None of the

ACEC land acquisitions would substantively impact any of the resources of concern for the respective ACECs. The diesel alternatives would not require any acquisition of ACEC lands.

Table 3.3-12 Summary of ACEC Land Acquisition Requirements for All Alternatives

	ACEC Lands	
Alternative	**Acquisition Area (acres)**	**Number of Parcels**
No-Build	0	0
Stoughton Electric	0.50	1
Stoughton Diesel	0	0
Whittenton Electric	0.50	1
Whittenton Diesel	0	0

Property Acquisition

In addition to open space analysis, a land use impacts analysis was conducted to determine if property acquisition would be required, and identify the ownership and use of parcels designated for acquisition. Final engineering plans may show an increase or decrease of the actual area of acquisition required.

No-Build (Enhanced Bus) Alternative

No new construction or land acquisition would be required for the No-Build Alternative. Therefore, the No-Build Alternative would have no direct impacts on land use.

Build Alternatives

The Build Alternatives would all require property acquisitions outside existing rights-of-way to accommodate the new stations and rail infrastructure. Summary tables of property impacts by municipality for the Stoughton Alternatives (Diesel and Electric) and Whittenton Electric Alternative are provided in Table 3.3-13.

The total acreage of property acquisition impacts of the Stoughton Electric Alternative (136.7 acres) and Whittenton Electric Alternative (136.8 acres) are nearly identical. The diesel versions of the rail alternatives result in 2.2 fewer acres of impact because of the need for traction power substations with the electric alternatives.

Table 3.3-13 Build Alternatives: Land Acquisition Summary by Municipality

Municipality	Public Ownership Area in acres (number of parcels)	Private Ownership Land Use Area in acres (number of parcels)				
		Commercial	Industrial	Residential	Undeveloped	Subtotal
Alignment						
Stoughton Alts.	4.1 (13)	0.9 (10)	11.8 (12)	15.7 (32)	15.2 (26)	43.6 (80)
Whittenton Alts.	2.2 (9)	9.0 (8)	14.6 (19)	13.7 (21) -	16.0 (28)	53.3 (76)
Substations						
Stoughton Alts.	1.1 (2)	-	<0.1 (1)	<0.1 (2)	1.1 (4)	1.1 (7)
Whittenton Alts.	1.1 (2)	-	<0.1 (1)	<0.1 (2)	1.1 (4)	1.1 (7)
Stations						
Stoughton Alts.	1.2 (2)	20.9 (15)	6.8 (11)	0.1 (1)	33.5 (12)	61.3 (39)
Whittenton Alts.	1.1 (2)	20.2 (14)	10.9 (20) -	0.1 (1)	22.5 (11)	53.7 (46)
Layover Facilities						
Stoughton Alts.	5.9 (1)	-	18.4 (2)	-	-	18.4 (2)
Whittenton Alts.	5.9 (1)	-	18.4 (2)	-	-	18.4 (2)
TOTAL						
Stoughton Alts.	12.3 (18)	21.8 (25)	37.0 (26)	15.8 (35)	49.8 (42)	124.4(128)
Whittenton Alts.	10.3 (14)	29.2 (22) -	43.9 (42)	13.8 (25)	39.6 (43)	126.5 (131)

Sources: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

Municipal Tax Loss

Property tax revenue data were obtained from review of on-line resources of the municipalities through which the alternatives pass. Estimates of annual (in 2009 dollars) property tax revenue loss from parcels were made based upon each municipality's property tax formula.

No-Build (Enhanced Bus) Alternative

No new construction or land acquisition would be required for the No-Build Alternative. There would be no impacts to property tax revenues.

Build Alternatives

Table 3.3-14 provides a comparative summary of the direct and indirect impacts to the social and economic environment potentially resulting from the Build Alternatives. There is no difference between the electric and diesel options for each Build Alternative.

The variations in property tax revenue losses do not correlate with the variations in private property acquisitions for each alternative. The Stoughton Alternatives would result in a greater amount of property tax revenue loss than the Whittenton Alternatives. Tax losses for both alternatives are dominated by the loss associated with the acquisition of the Fall River Depot Station site at $70,777—the single largest loss.

Table 3.3-14 Summary of Potential Effects to the Social and Economic Environment from All Alternatives

Alternative	Property Tax Revenue Loss[1]	Job Loss	Neighbor-hood Fragmentation	Residential Displacements (homes)	Business Displacements	Induced Jobs[3]	Induced Households[3]	Residential Property Value Change[2]
No-Build Alternative	0	No	None	0	0	0	0	No
Stoughton Alternatives	$197,251	Yes	Moderate	4	6	1,341	2,804	Yes
Whittenton Alternatives	$181,351	Yes	Moderate	3	6	1,341[4]	2,804[4]	Yes

1 Additional property tax revenue losses may result from small and/or partial acquisitions that cannot be determined at this phase.
2 Anticipated to increase in the vicinity of new stations and decrease in areas with moderate to severe noise impacts (railroad alignments and layover facilities).
3 Increase from No-Build Alternative; the total number of induced jobs and households is the same for Scenario 1 and 2.
4 Induced jobs and households for the Whittenton Alternatives were not estimated but are assumed to be similar to impacts of the Stoughton Alternatives.

All alternatives would result in job losses due to business displacements resulting from acquisition of private property with commercial lots for the station sites. It is not possible to project numbers of actual jobs lost at this phase of analysis, but only a few commercial buildings would be acquired and related job loss is assumed to be relatively minor. All Build Alternatives would result to a similar degree in residential displacements from acquisition of privately owned parcels with occupied residences. No-Build Alternative would result in community facility displacements.

Based on a review of residential and commercial property availability,[22] communities that would be impacted by residential displacements (Raynham) or business displacements (Fall River) have sufficient real estate capacity to absorb these displacements.

There are moderate differences in neighborhood fragmentation effects between the rail alternatives. Where active rail service is currently provided (Fall River Secondary, New Bedford Main Line, Attleboro Secondary, active portion of Stoughton Line, and Northeast Corridor), no neighborhoods would be fragmented by the construction, reconstruction, or operation of the commuter rail service. Where rail lines are out-of-service (inactive portion of Stoughton Line and Whittenton Branch) or have never previously existed, varying degrees of neighborhood fragmentation may result. Along the inactive portion of the Stoughton Line, some residential and commercial activity encroachment into the right-of-way has occurred, and over time some neighborhoods on either side of the alignment have developed continuity across the inactive railroad bed as residents have used the alignment for pedestrian transit. This appears to have been less common along the out-of-service Whittenton Branch, where residential neighborhoods tend to be located on one side of the alignment or the other. Accordingly, there would be less of a neighborhood fragmentation effect along the Whittenton Branch.

[22] Online research of residential real estate property availability conducted by reviewing current listings of similar homes (based on zoning of affected properties) in the affected communities at www.realtor.com. Commercial real estate vacancy rates conducted by telephone inquiries to chambers of commerce in the affected communities.

Protected Public Water Supply Land Impacts

This section discusses potential direct and indirect effects on water resource including protected public water supply lands. Surface and groundwater resources are protected under several state and federal regulatory programs, including the federal Clean Water Act (Section 404) and the Massachusetts Clean Waters Act (MGL Chapter 21, §26-53). Other applicable regulations include the Massachusetts Section 401 Discharge Regulations (314 CMR 9.00), Groundwater Quality Standards (314 CMR 6.00), Surface Water Quality Standards (314 CMR 4.00), and Wetland Protection Regulations (310 CMR 10.00). The limits of work proposed for each alternative were assumed to be the maximum extent of direct impacts.

No-Build Alternative

The No-Build Alternative does not include capital improvements that could increase impervious surface cover and impact water resources.

Build Alternatives

All of the Build Alternatives would have the potential to affect waterbodies and drinking water protection areas. All would require construction within public water supply Zone I areas, which is the area within 400 feet of a well that is generally afforded the greatest protection from development. All would upgrade existing transit corridors, which would have a negligible effect on pollutant loading. The Build Alternatives would build new rail lines on disused rail corridors, potentially introducing new pollutant sources in those areas. With mitigation and drainage features in place, none of the Build Alternatives are expected to impair any water resources. Potential impacts to the Hockomock Swamp and Fowl Meadow ACEC would occur due to stormwater discharges to Black Brook and the East Branch of the Neponset River, respectively from the Stoughton and Whittenton Alternatives. However, minimal impacts to ACECs from stormwater discharges would occur from the project. None of the above-mentioned discharges are associated with constructed stations, station platforms or parking areas. These discharges would primarily occur from conveyed overland flow from ditches along the railroad, which would carry negligible pollutant loads (with the exception of sediment). None of the proposed actions are expected to impair surface or groundwater resources within the ACEC. Compliance with the Massachusetts Stormwater Management Standards is provided for all stations except Stoughton and Dana Street. Compliance will be documented for these stations (as necessary) during later project design phase phases.

Stoughton Electric Alternative—The Stoughton Electric Alternative would involve construction within Zone II areas for six wells, and the IWPA for two wells. These areas would be disturbed only temporarily and would not receive any long-term impacts. This alternative would also require stormwater discharges to Zone II areas for six wells, the IWPA for two wells, and 10 different waterbodies, including one ORW within the Hockomock Swamp ACEC and the East Branch of the Neponset River in the Fowl Meadow ACEC. No Zone I areas would be affected by the construction on this line.

Along the Fall River Secondary no Zone A areas or groundwater protection areas (Zone I, Zone II, etc.) would be crossed by this line or receive any stormwater discharges. The stormwater discharges from the New Bedford Main Line would not be expected to contribute contaminants that would impair any waterbodies or water supplies. The existing stormwater discharges to the Zone A area for Fall Brook, Assawompset Pond, Long Pond, and Pocksha Pond would continue, but there would be no new impervious surfaces or pollutant sources tributary to this Zone A area. Due to the low potential for pollutant generation on the rail line, no impacts are expected to groundwater quality.

No electrical substations would be located in any IWPAs, Zone I areas, or Zone A areas. One electrical substation would be located in the Zone II for Easton GP Wells #1, #2, and #4 and would include secondary containment to minimize the risk of any surface or groundwater contamination from this location. With stormwater management measures in place, none of the stations or layover facilities is expected to impair any surface or groundwater resources. With mitigation and drainage features in place, the Stoughton Electric Alternative is not expected to impair any surface or groundwater resources.

Stoughton Diesel Alternative—The Stoughton Diesel Alternative would be comprised of the same elements as the Stoughton Electric Alternative as listed above and would have the potential to affect the same water resources. The Stoughton Diesel Alternative would have a slightly greater potential for pollutant loading due to the use of diesel fuel.

Whittenton Electric Alternative—The Whittenton Electric Alternative would involve construction within one Zone A area, the Zone I area for one well, Zone II areas for 10 wells, and the IWPA for two wells. These areas would be disturbed only temporarily and would not receive any long-term impacts. One new station, Easton Village Station, would be located in a Zone II area but would not have any impact on groundwater quality. This alternative would also require stormwater discharges to the Hockomock Swamp ACEC and the East Branch of the Neponset River in the Fowl Meadow ACEC.

While much of the rail corridor for this alternative already conveys diesel rail traffic under existing conditions, using the Whittenton Branch and reconstructing the Stoughton Line south of Stoughton Station would reintroduce rail traffic to a historic rail corridor. However, the Whittenton Electric Alternative is not expected to contribute contaminants that would impair surface or groundwater resources. The proposed drainage design includes measures to control new potential pollutant sources and would meet Massachusetts Stormwater Management Standards.

Along the Fall River Secondary no Zone A areas or groundwater protection areas (Zone I, Zone II, etc.) would be crossed by this line or receive any stormwater discharges. The stormwater discharges from the New Bedford Main Line would not be expected to contribute contaminants that would impair any waterbodies or water supplies. The existing stormwater discharges to the Zone A area for Fall Brook, Assawompset Pond, Long Pond, and Pocksha Pond would continue, but there would be no new impervious surfaces or pollutant sources tributary to this Zone A area. Due to the low potential for pollutant generation on the rail line, no impacts are expected to groundwater quality.

No electrical substations would be located in any IWPAs, Zone I areas, or Zone A areas. One electrical substation would be located in the Zone II for Easton GP Wells #1, #2, and #4 and would include secondary containment to minimize the risk of any surface or groundwater contamination from this location. With stormwater management measures in place, none of the stations or layover facilities is expected to impair any surface or groundwater resources.

With mitigation and drainage features in place, the Whittenton Electric Alternative is not expected to impair any surface or groundwater resources.

Whittenton Diesel Alternative—The Whittenton Diesel Alternative would be comprised of the same elements as the Whittenton Electric Alternative as listed above and would have the potential to affect the same water resources. The Whittenton Diesel Alternative would have a slightly greater potential for pollutant loading due to the use of diesel fuel.

Summary

The Whittenton Alternatives would be constructed and operated within a greater number of water protection zones. With regard to public water supply resources it is noted that the Whittenton Alternatives would require construction within public water supply Zone 1 areas (i.e. within 400 feet of the well), whereas the Stoughton Alternatives would avoid construction within public water supply Zone 1 areas. With mitigation and drainage features in place, none of the Build Alternatives are expected to impair any surface or groundwater resources.

Vibration Impacts

No-Build (Enhanced Bus) Alternative

Under the No-Build Alternative there would be no vibration impacts.

Build Alternatives

The Whittenton Alternatives result in 48 more impacted receptors than the Stoughton Alternatives, with the Attleboro Secondary segment of the Whittenton Alternatives being the primary cause of the greater impacts (Table 3.3-15). The noted vibration levels reflect annoyance and would not rise to a level considered to cause structural damage.

Table 3.3-15 Summary of Potential Vibration Impacts without Mitigation by Alternative

Alternative	Impacted Residences
No-Build (Enhanced Bus) Alternative	0
Stoughton Alternatives	369
Whittenton Alternatives	417

Noise Impacts

The noise analysis for the South Coast Rail project identified potential noise impacts by comparing the existing sound levels to projected future sound levels. The projected future noise levels would impact the human environment. There were two levels of impact (severe and moderate).

No-Build (Enhanced Bus) Alternative

Under the No-Build Alternative there would be no noise impacts.

Build Alternatives

Table 3.3-16 summarizes the total number of moderate and severe noise impacts by alternative for the operations of the rail line. All of the severe noise impact locations were evaluated for noise mitigation measures.

Stoughton Alternative—The Stoughton Electric Alternative (Stoughton, Southern Triangle-Fall River, and Southern Triangle-New Bedford segments) would result in 1,106 moderate and 341 severe impacts to residential receptors. The diesel operations would have similar impacts, with 1,085 moderate and 344 severe impacts.

Table 3.3-16 Summary of Projected Noise Impacts for South Coast Rail Alternatives

Alternative	Electric Alternative			Diesel Alternative		
	Moderate Impacts	Severe Impacts	Total	Moderate Impacts	Severe Impacts	Total
No-Build	0	0	0	0	0	0
Stoughton						
Stoughton	404	159	563	330	128	458
Southern Triangle - Fall River	466	135	601	570	181	751
Southern Triangle - New Bedford Main Line	236	47	283	185	35	220
Total	**1,106**	**341**	**1,447**	**1,085**	**344**	**1,429**
Whittenton						
Stoughton*	359	164	523	279	109	388
Whittenton	171	35	206	194	42	236
Southern Triangle - Fall River	466	135	601	570	181	751
Southern Triangle - New Bedford Main Line	236	47	283	185	35	220
Total	**1,232**	**381**	**1,613**	**1,228**	**367**	**1,595**

* Excludes the portion of the Stoughton line that is bypassed by the Whittenton Alternative (south of Raynham Junction).

Whittenton Alternative—The Whittenton Electric Alternative (Stoughton partial, Whittenton, Southern Triangle-Fall River, and Southern Triangle-New Bedford segments) would result in 1,232 moderate and 381 severe impacts to residential receptors. The diesel operations would have lower impacts, with 1,228 moderate and 367 severe impacts.

Summary

The Whittenton Alternative has the greatest track-related noise impacts (166 more impacts than the Whittenton Alternative), largely associated with the Whittenton Branch and the Attleboro Secondary Branch, which are located within densely populated areas. The Stoughton Alternative, by contrast traverses the Pine Swamp, a sparsely populated area located east of Taunton.

The diesel alternatives have somewhat lower noise impacts than the electric alternatives (18 fewer impacts) due to their slower operational speed compared to the electric alternatives.

Train Horn Noise

Severe noise impacts typically result from the close proximity to locomotive and rail car noise and from locomotive warning horns, which must be sounded one-quarter mile prior all public grade crossings. It should be noted that the majority of train horn impacts will occur at the same locations where rail operation impacts will occur. The train horn, however, is a uniquely different noise than the operations and was evaluated separately. A summary of these results can be found in Table 3.3-17. All of the severe noise impact locations were evaluated for noise mitigation measures.

Table 3.3-17 Summary of Projected Train Horn Noise Impacts for South Coast Rail Alternatives

Alternative	Moderate Impacts	Severe Impacts	Total
Stoughton			
Stoughton	437	457	894
Southern Triangle - Fall River	98	164	262
Southern Triangle - New Bedford Main Line	93	76	169
Total	**628**	**697**	**1,325**
Whittenton			
Stoughton*	368	374	742
Whittenton	460	708	1,168
Southern Triangle - Fall River	98	164	262
Southern Triangle - New Bedford Main Line	93	76	169
Total	**1,019**	**1,322**	**2,341**

* Excludes the portion of the Stoughton line that is bypassed by the Whittenton Alternative (south of Raynham Junction).

Train horns along the Stoughton Alternative would have 628 moderate and 697 severe impacts. The Whittenton Electric Alternative would result in the train horns producing 1,019 moderate and 1,322 severe impacts. The Whittenton Alternative results in the highest railroad grade crossing noise impacts.

In general, the Whittenton Alternatives have the greatest overall noise impact, both due to train movement and train horn usage at grade crossings.

Environmental Justice Impacts

This section compares the alternatives with regard to disproportionate adverse impacts to environmental justice populations, including property acquisition, change in noise or vibration levels or air quality, and the presence of traditional cultural properties and open space.

No-Build (Enhanced Bus) Alternative

Under the No-Build Alternative there would be no disproportionate impacts to Environmental Justice communities.

Build Alternatives

Impacts to environmental justice populations that would result from the South Coast Rail project are similar for all applicable resource topics with the exception of noise, as described below, and are summarized in Table 3.3-18.

Among the Build Alternatives, the Whittenton Alternatives would impact the greatest number of residences, and the Stoughton Alternatives the least. A greater percentage of noise and vibration impacts would be experienced by designated environmental justice populations under the Whittenton

Alternatives than the Stoughton Alternatives. This difference is attributable to the impacts of the Whittenton Alternative along the Attleboro Secondary through downtown Taunton.

Table 3.3-18 Summary of Adverse Effects on Environmental Justice Populations

Adverse Effects	No-Build	Stoughton Electric	Stoughton Diesel	Whittenton Electric	Whittenton Diesel
Neighborhood Disruption/Fragmentation	None	None	None	None	None
Residential Displacements	None	None	None	None	None
Business/Job Displacements[1]	None	Minimal	Minimal	Minimal	Minimal
Noise Impacts in Environmental Justice Neighborhoods (number of residences impacted by moderate and severe increases in noise levels)[2]	None	361	361	842	842
Percent of Total Noise Impacts in Environmental Justice Neighborhoods	None	25%	25%	30%	30%
Vibration Impacts in Environmental Justice Neighborhoods (impacted sensitive receptors)[3]	None	86	86	105	105
Percent of Total Vibration Impacts in Environmental Justice Neighborhoods	None	23%	23%	25%	25%

1 Business and job displacements would result from private property acquisition for the Fall River Depot Station, and would be minor as compared to the overall workforce in the surrounding community. See Chapter 4.2, *Land Use*, and Chapter 4.3, *Socioeconomics*.

2 Noise impacts data is based on the Stoughton and Whittenton Electric Alternatives; however the impacts of the diesel alternatives would be similar.

3 Diesel and electric vibration impacts would be the same.

Under all Build Alternatives and on a regional level, adverse noise impacts would not be disproportionately borne by state-listed environmental justice communities. However, on the municipal level, the analysis concludes that state-listed environmental justice populations in Fall River would experience disproportionately high and adverse noise impacts as compared to non-environmental justice populations under the Stoughton and Whittenton Alternatives prior to mitigation. Noise impacts to environmental justice and non-environmental justice areas would be mitigated.

Vibration impacts would be experienced across the region in both designated and non-designated environmental justice communities. Overall, adverse impacts would not be predominately borne by designated environmental justice communities under the Stoughton or Whittenton Alternatives. At the local level, designated environmental justice communities would experience a disproportionately high share of vibration impacts in Fall River under both the Stoughton and Whittenton Alternatives. Environmental justice communities in Taunton would experience a disproportionately high share of vibration impacts under the Whittenton Alternatives. Vibration impacts to environmental justice and non-environmental justice areas would be mitigated.

Loss of Priority Habitat

Rare species are considered an important environmental resource, protected under the Massachusetts Endangered Species Act and WPA. Temporary and permanent direct impacts to rare species and their habitat are anticipated for each of the alternatives. Direct impacts include impacts from construction, grading, vegetation management, and mortality associated with potential collisions with rail traffic. These activities may result in degradation of ecological function, loss of habitat, as well as loss of rare plant and animal species.

This section also describes the amount of 'barrier effect' for each alternative. A railroad corridor may act as a barrier that interferes with the movement of some mammals, amphibians, birds and reptiles from one habitat to another. The width of a railroad corridor can influence the frequency of wildlife crossings, as well as the mortality associated with potential collisions with rail traffic. The rail itself can create a barrier to smaller species such as amphibians, reptiles, and smaller mammals.

Table 3.3-19 summarizes the results of this analysis.

Table 3.3-19 Direct and Indirect Effects to Rare Species from the South Coast Rail Alternatives

Alternative	# of Priority Habitat (PH)	# of Rare Species Impacted	Migratory Route (Barrier effec t)
No-Build Alternative	0	0	0 miles
Stoughton Electric Alternative	5	8	3.2 miles
Stoughton Diesel Alternative	5	8	3.2 miles
Whittenton Electric Alternative	6	8	3.6 miles
Whittenton Diesel Alternative	6	8	3.6 miles
Stations	0	--	0 miles
Layover Facilities	0	--	0 miles

No-Build (Enhanced Bus) Alternative

None of the proposed park-and-ride facilities are within Estimated and Priority Habitats. Therefore, none of the components of the No-Build Alternative are expected to impact rare species and/or their habitat.

Build Alternatives

All Build Alternatives could impact eight state listed species, and would result in the loss of migratory route habitat because all rail alternatives require construction of new rail lines where currently there are none. An overview of potential direct and indirect effects is presented in Table 3.3-21.

Both Stoughton Alternatives would result in the loss of migratory route habitat (barrier effect) of approximately 3.2 miles.

Both Whittenton Alternatives would result in the loss of migratory route habitat (barrier effect) of approximately 3.6 miles.

In summary, the Whittenton Alternative would have greater impacts on Threatened and Endangered Species with a 11 percent greater barrier effect compared to the Stoughton Alternatives. The diesel alternatives would have slightly less potential impacts compared to the electric alternatives.

Impacts on Biodiversity

A comparison of the effects of the South Coast Rail alternatives on biological diversity (plant, wildlife and fish communities and habitats) is shown in Table 3.3-20.

Table 3.3-20 Summary of Environmental Consequences on Biodiversity

Alternative	Upland Habitat Loss (ac.)	Wetland Habitat Loss (ac.)	Fragmentation	Vernal Pool Habitat Loss (ac.)[1]	Loss of Surrounding Vernal Pool Upland Habitat[2] (ac.)
No-Build	0	0	No	0	0
Stoughton Electric	182.27	12.3	Yes	1.43	43.40
Stoughton Diesel	178.78	12.3	Yes	1.43	43.40
Whittenton Electric	187.98	11.2	Yes	0.8	41.61
Whittenton Diesel	183.87	11.2	Yes	0.8	41.61

1 Includes impacts (fill) to vernal pools and to any wetland area within 100 feet of the boundary of a vernal pool, where the pool is within a wetland.

2 Loss of supporting vernal pool upland habitat includes loss of buffer habitat defined as loss of forested wetland within 100 feet of VHP, and includes loss of upland habitat defined as upland habitat loss calculated for forested upland habitat between 100 and 750 feet of a vernal pool.

No-Build (Enhanced Bus) Alternative

The No-Build Alternative would not impact natural communities or biodiversity.

Build Alternatives

All Build Alternatives would result in the loss of upland habitat, wetland habitat, and vernal pool habitat (including direct and indirect impacts to vernal pools as well as supporting upland habitat used by vernal pool amphibians). All Build Alternatives, would result in habitat fragmentation and would create or exacerbate a barrier to wildlife movement (see Section 4.14.3).

Stoughton Electric Alternative—The Stoughton Electric Alternative includes improvements to existing active freight or rail lines from Canton Junction to Stoughton Station, and on the two Southern Triangle segments (the Fall River Secondary and New Bedford Main Line), as well as restoring out-of-service rail line from Stoughton Station to Longmeadow Street in Taunton. This alternative would include constructing a trestle through part of the Hockomock Swamp to reduce impacts to wetlands, biodiversity, and rare species.

Hockomock Swamp and Pine Swamp have been identified as areas of concern for biodiversity impacts. Potential impacts could include direct loss of habitat, fragmentation (either by creating a canopy gap or reducing the ability of wildlife species, including state-listed rare species, to cross the rail bed), introduction of invasive species, and increased noise.

The Stoughton Alternatives would exacerbate existing fragmentation of wetland and upland communities, particularly through the Hockomock Swamp and Pine Swamp, although the barrier effect would be reduced by constructing a trestle in the Hockomock Swamp.

The majority of this would result from reconstructing the Stoughton Line. This segment of the Stoughton Electric Alternative would increase habitat fragmentation (the existing rail bed, although out-of-service, has fragmented habitats and acts as a barrier to some organisms) within the Hockomock Swamp ACEC and the Pine Swamp. This barrier may affect several vernal pool complexes.

Stoughton Electric Diesel Alternative—The Stoughton Diesel Alternative would result in similar impacts to biodiversity as the Stoughton Electric Alternative. Because it would not require electrical power substations, the Stoughton Diesel Alternative would result in 3.49 acres less upland habitat loss, and 0.01 acre less wetland habitat loss when compared to the Stoughton Electric Alternative.

Whittenton Electric Alternative—The Whittenton Alternative includes improvements to existing active freight or rail lines from Canton Junction to Stoughton Station, along the Attleboro Secondary through downtown Taunton, and on the two Southern Triangle segments (the Fall River Secondary and New Bedford Main Line), as well as restoring out-of-service rail line from Stoughton Station to Raynham Junction on the Stoughton Line and along the out-of-service Whittenton Branch in Raynham and Taunton. This alternative would include constructing a trestle through part of the Hockomock Swamp to reduce impacts to wetlands, biodiversity, and rare species.

Areas subject to biodiversity impacts have been identified as the Hockomock Swamp, and the private land adjacent to the right-of-way near Prospect Pond in Taunton. Potential impacts could include direct loss of habitat, fragmentation (either by creating a canopy gap or reducing the ability of wildlife species, including state-listed rare species, to cross the rail bed), introduction of invasive species, and increased noise.

The Whittenton Alternatives would fragment wetland and upland communities, particularly through the Hockomock Swamp and along the Whittenton Branch, although the barrier effect would be reduced by constructing a trestle in the Hockomock Swamp. The majority of this would result from reconstructing the Stoughton Line north of Raynham Junction

It would also result from reconstructing the Whittenton Branch from Raynham Junction to Whittenton Junction. This segment of the Whittenton Electric Alternative would increase habitat fragmentation (the existing rail bed, although out-of-service, has fragmented habitats and acts as a barrier to some organisms). This barrier may affect vernal pools adjacent to the alignment.

The Hockomock Swamp ACEC is the only ACEC that would be impacted by the Whittenton Alternatives. Approximately 0.14 acre of vernal pool habitat, 2.31 acres of buffer habitat, and 6.12 acres of upland habitat would be impacted within the Hockomock Swamp ACEC.

Whittenton Diesel Alternative—The Whittenton Diesel Alternative would result in similar impacts to biodiversity as the Whittenton Electric Alternative. Because it would not require power substations, the Whittenton Diesel Alternative would require 4.11 acres less upland habitat loss, and 0.01 acre less wetland habitat loss, when compared to the Whittenton Electric Alternative.

In summary, the Whittenton Alternatives would have 1.1 acres less wetland loss than the Stoughton Alternatives and 0.63 acre less vernal pool wetland habitat loss than the Stoughton Alternatives. Overall, the diesel alternatives would have slightly less impact compared to the electric alternatives. The Stoughton Alternatives would result in approximately 5 acres less Upland Habitat loss than the Whittenton Alternatives.

Impacts on Biodiversity—CAPS Analysis

The University of Massachusetts' Conservation Assessment and Prioritization System (CAPS) model was used as a supplemental method of evaluating indirect impacts to biodiversity. CAPS is a software program designed to assess the ecological integrity and biodiversity value of every location based on

natural community-specific models. It is typically used to help prioritize lands for conservation action based on their assessed ecological value and provides a quantitative assessment of ecological integrity that can be used to compare various scenarios. The CAPS model was used to analyze the impacts of the South Coast Rail alternatives on ecological integrity taking into account both their physical barrier effects (measured as the presence or absence of rail tracks and ballast, the number of tracks, the presence and height of a trestle, and the presence and height of retaining walls) and their noise or disturbance effects (measured as the number of trains per day and the number of cars per train).

The CAPS analysis results showed similar impacts of the Stoughton and Whittenton Alternatives on ecological integrity, with the Whittenton Alternatives showing a slightly higher loss of Index of Ecological Integrity (IEI) Units compared to the Stoughton Alternatives. The trestle through the Hockomock Swamp would reduce the biodiversity effects for either the Stoughton or Whittenton Alternatives. A discussion of the CAPS analysis is presented in Chapter 4.14, *Biodiversity*.

The Stoughton and Whittenton Alternatives would equally reduce connectivity in the Hockomock Swamp with a gradient ranging from major impacts close to the rail line to negligible impacts at greater distances, compared to the existing connectedness. Without a trestle, these alternatives would result in substantial losses in connectivity in the Hockomock Swamp east of the rail line, between the former Raynham Greyhound Track and Foundry Street and between the rail line and Route 138, and in some areas west of the rail line. Moderate impacts would extend through much of the Hockomock, including areas east of Route 138. These impacts would be reduced by the trestle, with major losses restricted to a smaller area east of the rail line and north of the former Raynham Greyhound Track. Impacts would also extend over a smaller area compared to the “no-trestle” option.

The restoration of commuter rail through Pine Swamp in Raynham, for the Stoughton Alternatives, would result in a decrease in connectivity throughout the swamp when compared to the existing connectedness. The effect is moderate, with some higher areas of decrease occurring west of the rail line.

While a useful tool for considering landscape-level impacts and relative comparison of scenarios, there are several important limitations to the CAPS analysis. CAPS as applied to this project does not account for the effects of the existing railroad grade on overall landscape condition, as the analysis tool does not have this level of granular information. The CAPS analysis also does not take into account existing uses of the right-of-way, such as ATVs and their effect on ecological integrity (both in terms of physical disruption and noise disturbance). These frequent uses of the existing grade itself also serve to maintain at least a partial canopy gap, particularly north of the existing power line and also adjacent to portions of the existing Raynham Park racetrack. The CAPS program software does not account for these disruptive and fragmenting conditions and instead treats the Hockomock Swamp in its current condition as a single, unfragmented, continuous, uniformly intact habitat. Thus while it provides a measure of the potential benefits of the trestle, CAPS seemingly overestimates and overstates the existing ecological integrity of Hockomock and Pine swamps, and thus likewise overestimates the effects of South Coast Rail alternatives on ecological integrity.

Cultural Resources Impacts

This section identifies the potential direct and indirect, as well as the permanent and temporary construction impacts to historic and archaeological resources from implementation of the South Coast Rail alternatives. For each alternative and segment or element of alternative (e.g. station), direct, impacts on historic resources were analyzed.

No-Build Alternative

No impacts would result from construction and operation of the No-Build Alternative.

Build Alternatives

The overall impacts to historic and archaeological resources resulting from improving or constructing the Build Alternatives vary considerably between the alternative alignments (see Table 3.3-21).

Each of the alternatives would be similar in their adverse effects to historic structures. The majority of these effects, for all alternatives, would result from reconstructing historic bridges to accommodate an additional track, or to meet Federal Railroad Administration loading standards for commuter rail trains.

Each of the alternatives would also result in indirect impacts to historic properties as a result of a change in setting (visual impacts) or increased noise (which could affect a quiet setting or could result in noise mitigation that would alter the appearance or setting of a structure). These indirect effects (only visual, only noise, or a combination of the two) would impact the largest number of properties (72) for the Whittenton Electric Alternative.

Each of the alternatives would also have the potential to affect as yet to be determined archaeological resources and areas of archaeological sensitivity (which would require further investigation to determine if archaeological resources were present).

Adverse effects, including unanticipated discoveries will be further addressed through a Programmatic Agreement, a draft of which is included in Appendix 4.8-A.

Table 3.3-21 Summary of Potential Impacts to Historic and Archaeological Resources

Alternative	Historic Resources				Archaeological Sites
	Direct Impacts	Indirect Impacts			Recommended as Eligible
		Visual	Noise	Noise + Visual	
No-Build	0	0	0	0	0
Stoughton Electric	5	25	0	35	10
Stoughton Diesel	5	9	16	19	10
Whittenton Electric	5	32	0	33	11
Whittenton Diesel	5	11	14	19	11

Based on a comparison of the results of the Intensive Archaeological Survey on the Stoughton Line between Route 138 and Weir Junction, and the Whittenton Alternatives within the same section, the Whittenton Alternatives would have greater impacts to archaeological resources recommended as eligible for the National Register.

The Stoughton Alternatives would likely affect three sites: the King Philip Street Site and the Chickering Road site , and the East Brittania Street Site. Each of these sites yielded a low density of quartz chipping debris and other stone tools (a broken rhyolite point tip and an argillite cobble cortex, and a quart scraper). These three sites show evidence of stone tool manufacturing/maintenance.

The Whittenton Alternatives would affect three sites near the northern end of the Whittenton Branch: the Mel's Diner Site, Brown Couch Site, and ATV Site. Each of these yielded a low density of quartz chipping debris, and one granite hammerstone. These sites appear similar to the Pine Swamp sites.

More importantly, the Whittenton Alternatives would likely affect the Cedar Swamp Site, potentially related to a known Village Site. The Cedar Swamp Site yielded a more complex array of pre-contact materials, including quart chipping debris, an argillite flake, a chert flake, fire-cracked rock, and a "bowl-shaped cultural feature" potentially associated with a hearth.

Based on this information, the Whittenton Alternatives likely have greater adverse effects to cultural resources protected under Section 106 of the National Historic Preservation Act than do the Stoughton Alternatives.

3.3.3.3 Other Environmental Impacts

In addition to the benefits and impacts described above, other impacts were analyzed as well that are considered in the overall evaluation of environmental impacts of the alternatives.

Transportation

No-Build (Enhanced Bus) Alternative

Under the No-Build Alternative no impacts would occur to the regional highway system; however the benefits to the regional highway system provided by the Build Alternatives (discussed below) would not be realized. No impacts to grade crossings would occur and local intersections would not be impacted, other than impacts associated with background growth through 2035.

Build Alternatives

The traffic analysis evaluated the traffic impacts of each of the commuter rail stations proposed as part of the Build Alternatives. Additionally, regional highway operations were evaluated to determine projected benefits of the regional transit enhancement associated with each of the alternatives. Traffic conditions in the vicinity of each station and along the regional highway network were analyzed for existing conditions and future 2030 conditions with and without the project. Mitigation would be implemented for roadways and intersections that would be most impacted by traffic associated with commuter rail stations associated with rail alternatives. In cases where Build Alternatives-related traffic would result in a degradation of operating conditions when compared to the No-Build Alternative, mitigation measures were evaluated and would be implemented to address these impacts. An overview of each impact category is provided below.

Traffic Impacts associated with Grade Crossings

The Build Alternatives would have similar impacts on public grade crossings that would be in service along the Build Alternatives. A total of 52 existing active public grade crossings are present along the alignments of the Build Alternatives. Of these, four public crossings would be recommended for closure along the Fall River Secondary, which is common to all Build Alternatives.

The Stoughton Alternative would result in 43 active public grade crossings, and the Whittenton Alternative would result in 50 active public grade crossings. The Build Alternatives will require gates at grade crossings within Taunton, Raynham, Easton, Stoughton and Canton to be closed approximately six

times an hour, or approximately 10 percent of the peak hour. Two grade crossings are uniquely associated with the Whittenton Alternative and consist of the reactivation of two inactive grade crossings at Whittenton Street and Warren Street.

Traffic Impacts in Station Areas

The Build Alternatives would have similar impacts on intersections near stations along the Build Alternatives. The Whittenton Alternative would have impacts at the Dana Street Station while the Stoughton Alternative would have impacts at the Taunton Station. Impacts in both station areas would be effectively mitigated, as for all other impacted station areas.

No significant parking, bicycle and pedestrian impacts would be associated with the Build Alternatives, which would be similar in their extent of impact.

Impacts on Freight Operations

Feasible scenarios could be developed that would enable co-existence of freight operations and the Build Alternatives without impacting freight operations. While during the construction process of the Build Alternatives, freight operations would be temporarily impacted, the operation of the Build Alternatives would not interfere with freight operations. The permanent long-term infrastructure improvements to the rail network associated with the Build Alternatives would also benefit freight operations.

Visual and Aesthetic Resources

No-Build (Enhanced Bus) Alternative

The existing highway alignments that would be used by the No-Build (Enhanced Bus) Alternative present a visually disturbed environment from natural conditions. The alignments would not change and no new highway construction would be required for the No-Build Alternative. Using these highways for this alternative would not affect any visual or aesthetic resources.

Additional signage may be installed at the park-and-ride/bus facilities used by this alternative to direct motorists to parking areas. The impacts to the visual environment from streetscape changes as a result of potential park-and-ride lots/bus station expansions would be an incremental addition to the existing conditions.

Build Alternatives

The overall impacts to visual and aesthetic resources resulting from improving or constructing the Build Alternatives would not vary considerably between the alternative alignments. All Build Alternatives are rated with an overall moderate visual impact.

Both alternatives would require track and crossing upgrades, generally located in active, disturbed environments including rural and urban settings with one crossing of a designated “Wild and Scenic River” by the Fall River Secondary (see Chapter 4.10, *Open Space*). Stations and layover facilities would be located in developed or partially developed areas. The Weaver’s Cove East layover facility would be located near a Wild and Scenic River, resulting in moderate visual impacts. Tracks, stations and layover facilities would all have minimal to moderate visual impact, unless as noted otherwise below

Both the Stoughton and Whittenton Alternatives would substantially impact the visual environment at the historic Easton train station.

Both alternatives would substantially impact the visual environment in currently out-of-service segments for approximately 15 miles. For the Stoughton Alternative this includes the segment of the Stoughton Line through Pine Swamp, east of Taunton and for the Whittenton Alternative this includes the Whittenton Branch, located in the western portion of Taunton.

Common to both alternatives is the trestle through Hockomock Swamp, north of Taunton. Public views of the proposed 1.6-mile trestle would be limited throughout the Hockomock Swamp wildlife management area and will have a visual impact; however there is limited public access to this area.

Electric alternatives would have higher visual impacts than diesel alternatives due to the electrical infrastructure requirements (i.e. overhead catenary).

Farmland

This Section evaluates the specific impacts of each of the proposed alternatives to designated areas of mapped farmland soils.

No-Build (Enhanced Bus) Alternative

The No-Build Alternative (Enhanced Bus) would consist of enhancing current bus service along existing roads and highways. None of three existing park-and-ride facilities that would be modified as part of the No-Build Alternative are within mapped areas of designated farmland soils. Under the No-Build Alternative, minor modifications are proposed to these existing parking lots that would not disturb additional land. No impacts to farmland soils are anticipated under the No-Build Alternative.

Build Alternatives

Potential impacts to mapped areas of designated farmland soils for each of the Build Alternatives is presented in Table 3.3-22. Using the USDA scoring system, the impacts to farmland soils along all Build Alternatives all received similarly low scores. Such scores indicate that these impacts would not be considered significant under the FPPA, and that mitigation for these losses would not be required for any of the Build Alternatives.

Table 3.3-22 Impacts to Designated Farmland Soils by Alternative (acres)[1]

Alternative	Southern Triangle	Northern Element	Stations	Total
No-Build/Enhanced Bus Alternative	--	--	--	0
Stoughton Electric Alternative	--	2.6	16.0	18.6
Stoughton Diesel Alternative	--	--	16.0	16.0
Whittenton Electric Alternative	--	2.6	16.2	18.8
Whittenton Diesel Alternative	--	--	16.2	16.2

Does not include potential mid-day layover facility impacts.

Stoughton Electric Alternative—The Stoughton Electric Alternative would result in impacts to 12.9 acres of designated farmland soils. Much of this impact occurs as a result of development of the North Easton and Taunton Depot station sites (7.3 and 5.7 acres, respectively).The remaining impacts occur as a result of the traction power stations associated with the electrification of the Stoughton Line and the development of the Freetown station site. One of the traction power stations (TPSS-1) is located within the Hockomock Swamp ACEC and would impact 1.1 acres of designated farmland soils.

Stoughton Diesel Alternative—The Stoughton Diesel Alternative would result in impacts to 10.3 acres of designated farmland soils. This impact is slightly less than the electrification alternative because there are no traction power stations required along the Stoughton Line under the diesel alternative. The remaining impacts occur due to development of the North Easton and Freetown station sites.

Whittenton Electric Alternative—The Whittenton Electric Alternative would result in impacts to 18.6 acres of designated farmland soils, the largest impact to farmland soils of all of the alternatives. Much of this impact occurs as a result of development of the North Easton and Taunton Depot station sites (7.3 and 5.7 acres, respectively). The remaining impacts occur as a result of the traction power stations associated with the electrification of the Stoughton Line and the development of the Freetown station site and the Dana Street Station site. One of the traction power stations (TPSS-1) is located within the Hockomock Swamp ACEC and would impact 1.1 acres of designated farmland soils.

Whittenton Diesel Alternative—The Whittenton Diesel Alternative would result in impacts to 16.0 acres of designated farmland soils. This impact is 2.6 acres less than for the Whittenton Electric Alternative, because no traction power stations would be required for the diesel alternative.

Summary

The Stoughton Alternative would have substantially less impact on designated farmland soils compared to the Whittenton Alternative (which has additional impacts associated with the Taunton Depot and Dana Street station sites). The diesel alternatives have slightly less impacts overall than the electric alternatives due to the absence of traction power stations.

Hazardous Materials

No-Build Alternative

The No-Build Alternative would not require acquisition of properties with Recognized Environmental Conditions (RECs) and therefore would not require remediation or soil/groundwater management during construction.

Build Alternatives

Each of the Build Alternatives would require acquisition of properties with Recognized Environmental Conditions (RECs) that would require further investigation. In each case, remediation or soil/groundwater management during construction could be required. Table 3.3-23 summarizes the number of RECs and the impact that were identified for each alternative.

Table 3.3-23 Summary of RECs by Alternative

Alternative	Total Number of Stations/Bypasses	Total Number of RECs	Number of Low Impact RECs	Number of Medium Impact RECs	Number of High Impact RECs
Stoughton Alternatives	11/0	29	5	18	6
Whittenton Alternatives	11/0	32	6	21	5

The Stoughton, and Whittenton Alternatives each have at least seven high impact RECs that were identified, and these alternatives also have the potential to encounter soil or groundwater contamination. Taunton Station on the Stoughton Alternatives, and Dean Street on the Whittenton Alternatives have three and one high impact RECs, respectively, that were identified.

The Stoughton Alternatives and the Whittenton Alternatives would have environmental benefits associated with remediating contaminated sites, particularly the station sites with known soil and groundwater contamination such as the Taunton station site. Each of the two layover sites associated with the Build Alternatives would involve acquisition of five properties with RECs that would require further investigation and potentially requiring remediation or soil/groundwater management during construction could be required.

The Stoughton and Whittenton Alternatives are similar with regard to their impact related to hazardous materials and would benefit environmental conditions through remediation of Recognized Environmental Conditions.

Geology

No-Build Alternative

The No-Build Alternative (Enhanced Bus) would consist of enhancing current bus service along existing roads and highways. Construction activities would be limited to the modification of three existing Park and Ride facilities, requiring limited clearing and excavation. No long-term changes would be expected to geologic structures or faults, to bedrock, soils, or geologic stability, to seismicity, or to the rock and soil units surrounding excavations.

Maintenance and development activities within the South Coast Rail project area would be expected to continue, and would create changes in the built environment, but would not adversely impact soils and geologic conditions. Normal geologic processes, such as erosion and sedimentation, would also continue. No specific impacts with respect to soils or geology would be anticipated under the No-Build Alternative.

Build Alternatives

None of the Build Alternatives would require tunneling or other deep excavation that would significantly affect geological conditions. Most disturbance activities would encompass a relatively small area within or adjacent to previously disturbed areas and infrastructure. These include active rail and abandoned rail beds (Stoughton line and Whittenton Branch) that have previously been established to be compatible with subsurface conditions. No long-term changes would be expected as a result of the Build Alternatives to geologic structures or faults, to bedrock, soils, or geologic stability, to seismicity, or to

the rock and soil units surrounding excavations. No long-term adverse impacts to soils and geology would occur with the Build Alternatives; therefore, no mitigation will be required.

Indirect Effects

Potential indirect effects (beneficial and adverse) of the rail alternatives were evaluated with and without smart growth measures (including TOD). The Corridor Plan was the guiding land use development plan for this analysis. Induced growth that would result from the rail alternatives includes the creation of new residential development and jobs. In order to assess the indirect effects of this induced growth, two scenarios were developed to allocate growth in the South Coast region. The first scenario, Scenario 1, allocates induced growth under business as usual conditions, includes baseline conditions, and assumes that induced growth would occur in a traditional pattern. The second scenario, Scenario 2, assumes that growth would be directed to Priority Development Areas (PDAs) and away from PPAs, based on the planning efforts of each municipality in the South Coast region.

Because the same level of induced growth distributed among the municipalities is expected for either the Stoughton or the Whittenton Alternatives, there would be no discernible difference in indirect effects under each alternative for purposes of comparison among the Build Alternatives. The indirect effects of the No-Build Alternative are reflected in the baseline growth through 2035. A resource-specific analysis of indirect effects is provided in Chapter 5.

Cumulative Impacts

Table 3.3-24 summarizes the incremental changes to the evaluated resources from the South Coast Rail alternatives that, in combination with past activities or trends and other known current and future projects, would potentially result in a substantive cumulative effect. The comparison is provided for both scenarios for the two alternatives considered in this evaluation, in relationship to the status of these resources under the projected No-Build Alternative conditions in 2035. Because there is no substantive difference between the impacts from rail alternatives' electric- or diesel-powered trains, these options are not included in this summary comparison.

Table 3.3-24 shows that in comparison to the No-Build Alternative, the Stoughton and Whittenton Alternatives would not have an adverse cumulative impact on the evaluated resources. There would be only minor differences in the cumulative effects of the Stoughton and Whittenton Alternatives, attributable to the minor differences in direct effects. For many resources, the cumulative impacts of Scenario 1 represent an insubstantial change from the conditions that would exist under the No-Build Alternative. In general, the cumulative effects of either alternative would be beneficial, depending upon the extent of implementation of Smart Growth measures.

Table 3.3-24 Summary of Cumulative Impacts

	Resource					
	Land Use	**Wetlands**	**Biodiversity**	**Protected Open Space**	**Air Quality**	**Economy**
No-Build Alternative	Conversion of 1,315 acres per year	No net loss policy	22 acres of land converted per day	Protected at average rate of 383.7 acres per year	Trend of increasing GHG emissions counteracted by new regulatory requirements	Population: 928,031

1 Annualized capital cost and annual operating and maintenance cost estimates divided by annual passengers.
2 New daily round-trip transit trips at proposed South Coast Rail stations
3 Additional property tax revenue losses may result from small and/or partial acquisitions.
4 Sites with the presence or likely presence of hazardous materials
5 Massachusetts General Law Chapter 91 is implemented by Massachusetts Regulations at 310 CMR 9.00 (Waterways Regulations). The purpose of Chapter 91 and the Waterways Regulation is to protect certain public rights that are inherent in tidal waters of the Commonwealth and certain non-tidal rivers and streams. New construction, changes in use or substantial expansions of existing structures within these jurisdictional areas require approval under these regulations.

3.3.4 APPLICANT'S PREFERRED ALTERNATIVE

The EPA regulations at 40 CFR part 230 (the Section 404(b)(1) Guidelines) state (230.10(a)):

> "...no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge, which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences."

This summary provides an overview of the alternatives. The first step in the alternatives analysis is to determine whether the alternative meets the project purpose. Based on the analysis it was determined that all four Build Alternatives meet the project purpose.

The second step in the evaluation determines whether an alternative is practicable. Based on the analysis it was determined that all four Build Alternatives are practicable.

The third step in the alternatives analysis includes two sub-criteria: beneficial environmental effects and environmental impacts. The full extent of this information is presented in Tables 3.3-24 and 3.3-25, in the preceding sections, and in Chapters 4 and 5 of this FEIS/FEIR. The results are summarized below.

3.3.4.1 Findings

Having determined that the Attleboro and Rapid Bus alternatives – including the various permutations of each – are not practicable alternatives, we are left to consider whether the Whittenton route, and diesel or electric mode of each, would have less adverse impact on the aquatic ecosystem than the alternative that is proposed (i.e., the applicant's preferred alternative), without having other significant adverse environmental consequences. We can conclusively state that the Stoughton Alternative meets the overall project purpose and that it is practicable. The Whittenton Alternative also meets the overall project purpose albeit to a lesser degree: It is predicted to have slightly lower overall ridership than the Stoughton Route, and in particular, it draws fewer riders from the target termini of New Bedford and Fall River. Some (notably, citizens and leaders of those cities) would argue that it therefore does not meet the intent of the overall project purpose: "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts, and to enhance regional mobility." On this point however, others have reasonably questioned whether a roughly 8-minute longer (one-way) daily commute would indeed cause the non-trivial reductions in ridership predicted by the models. The Corps has concluded that the Whittenton Alternative ridership numbers are not so low that this alternative could be considered as failing to meet the overall project purpose.

From this, we are left to determine whether the Whittenton Alternative is practicable. As previously mentioned, practicable means "available and capable of being done considering costs and logistics in light of overall project purposes" (40 CFR 230.10(a)(2). The Whittenton route is wholly owned by MassDOT and was in fact the route last used for passenger service between Boston and New Bedford up until 1958 when operations ceased. Therefore, it is unquestionably available. Moreover, the costs of the Whittenton Alternative are only marginally higher than would be the Stoughton Alternative, and are not the deciding factor with respect to practicability. The practicability of the Whittenton Route, then, rests on its logistical feasibility. Some commenters (notably, citizens and leaders of Taunton) have argued that it is not, based on the substantially higher number of at-grade crossings and the overall impacts to the already congested downtown Taunton area. Public safety is another issue with regard to logistics, and it is not a trivial matter that doubling the number of at-grade crossings in Taunton at least doubles the likelihood of a serious incident such as a life-threatening collision between a train and a vehicle or

person in that community. The Federal Railroad Administration has indicated that such situations are not ideal; however they also are not insurmountable from the perspective of general rail operations, and there are examples of municipalities with similar or greater logistical constraints than would be encountered in the City of Taunton under a Whittenton Alternative. Therefore, we conclude that the Whittenton Alternative is indeed a practicable alternative.

The determination, therefore, rests on a comparison of the overall environmental impacts of the Stoughton and Whittenton Routes (and diesel or electric modes). On initial inspection, it is readily seen that the Stoughton Alternative has greater impacts to aquatic resources – approximately 1.0 acre more wetland would be filled under the Stoughton Route than under the Whittenton Route. While both routes would affect Hockomock Swamp equally, the Whittenton route would bypass Pine Swamp and other wetlands north and south of Pine Swamp, and thus would result in fewer acres of wetland loss than would the Stoughton Route. As noted in the USEPA Guidelines, "no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, *so long as the alternative does not have other significant adverse environmental consequences"* (emphasis added). The Guidelines do not limit other significant adverse environmental consequences to the aquatic environment.

Thus the determination rests on whether the impacts to other environmental resources of the Whittenton route outweigh the slightly higher aquatic resource impacts of the Stoughton Route. Such environmental resource impacts are relevant to the natural environment in general and the human environment in particular. These include effects to cultural resources, public safety and environmental justice communities, and other environmental resource impacts including (but not limited to) air quality, water quality, endangered species, biodiversity and open space.

The four Build Alternatives are similar in the extent of their benefits and impacts, due to the fact that they differ for only a small portion of their alignments.

In terms of alignment, the Stoughton Alternatives would have greater benefits to the South Coast Rail communities with respect to transportation, air quality, and fewer noise impacts (particularly to Environmental Justice communities) than the Whittenton Alternatives. The Stoughton Alternatives serve more people with public transportation, more people from the South Coast communities, and provide the shortest travel time and the greatest benefit to the Freeway system. The Whittenton Alternatives would result in higher emissions of CO, NOx, VOCs, and CO2 than the Stoughton Alternatives, due to the difference in VMT and the greater reduction in VMT associated with the Stoughton Alternatives.

With the exception of having slightly less impact to aquatic resources, the Whittenton Alternative would have greater adverse impacts to the upland habitat of state-listed species and to ecological integrity as measured by the CAPS analysis. The Whittenton Alternative would have less impact to vegetated wetlands (1.0 acre) than the Stoughton Alternative, as a result of avoiding the wetlands between Route 138 in Raynham and Longmeadow Road in Taunton – including wetlands within Pine Swamp. The wetlands and vernal pools that have formed on the right-of-way between East Brittania Street and Thrasher Street (0.9 acre) represent the majority of impacts; the impacts in Pine Swamp are comparatively small, since the new rail service would be placed on existing fill (the former Old Colony Dighton & Somerset right-of-way corridor abandoned ca. 1916). Otherwise, both alternatives have the same impacts to waterways, wetlands, vernal pools and rare species habitat within the Hockomock Swamp Area of Critical Environmental Concern. The Stoughton Alternative would have less impact to ecological integrity (as demonstrated by the CAPS analysis) and to upland habitat of state-listed species

(Blandings turtles; *Emydoidea blandingii* and eastern box turtles; *Terrapene carolina*) than the Whittenton Alternative (see Table 3.3-26).

Table 3.3-26 Comparison of Aquatic and Biotic Resource Impacts

Resource	Whittenton Electric Alternative	Stoughton Electric Alternative	Whittenton Difference (amount of loss)
Waterways	1.8 ac	1.9 ac	-0.1
Wetlands (federal)	9.4 ac	10.4 ac	-1.0 ac
Wetlands and Waterways in Hockomock Swamp ACEC	1.7 ac	1.7 ac	0
Loss of Vernal Pool Habitat (fill placed in vernal pool)	0.36 ac	0.53 ac	-0.2 ac
Loss of Vernal Pool Habitat (fill placed in adjacent wetlands)	0.8 ac	1.43 ac	-0.6 ac
Rare Species Barrier Effect	3.6 miles	3.2 miles	+0.4 mile
Loss of Ecological Integrity (IEUs)- With Trestle	484.6	474.5	+10.1 IEUs

The Whittenton Alternative, because of its route through downtown Taunton and the number of grade crossings in this segment, would have greater adverse noise impacts to populated areas in general and environmental justice populations in particular. An additional 1,341 residences would experience noise impacts, of which 481 would be minority or low-income families. As shown below in Table 3.3-27, the combined moderate and severe noise impacts (including the Southern Triangle) would be substantially higher for the Whittenton Alternative—with a 93 percent increase in the noise impacts to environmental justice residences. The Whittenton Alternative would also have greater vibration impacts in environmental justice areas than the Stoughton Alternative (105 compared to 86). While vibration impacts under both the Stoughton and Whittenton Alternatives would disproportionately impact environmental justice areas in Fall River, the Whittenton Alternative would also disproportionately impact environmental justice areas in Taunton.

Table 3.3-27 Comparison of Noise Impacts—Environmental Justice Populations

Noise Impacts	Whittenton Alternative	Stoughton Alternative	Whittenton Difference
Environmental Justice Residences	842	361	+ 481 (133%)
Non-Environmental Justice Residences	1,945	1,085	+ 860 (79%)
Total Residences	2,787	1,446	+1,341 (93%)

Note: Includes both moderate and severe impacts from train operation, plus horn noise impacts.

We also find that the Whittenton Alternative would result in greater overall air quality impacts than would the Stoughton Route. The result of the Whittenton Alternative would be that more vehicles would remain on the highways and thus there would be more VMT under a Whittenton option than under a Stoughton option, resulting in greater greenhouse gas emissions.

To be sure, the greater impacts to wetlands along the Stoughton Route are not trivial; however the loss of 1.0 more acre of wetlands must be weighed against the higher impacts to biodiversity, threatened and endangered species, air quality and cultural resources associated with the Whittenton Alternative.

Thus a comparison of the comprehensive environmental impacts (including secondary and cumulative impacts) of the Stoughton and Whittenton Alternatives leads us to conclude that, overall, there is no less environmentally damaging alternative than the Stoughton Alternatives. Furthermore, in terms of propulsion technology (electric or diesel) the diesel alternative has a greater overall impact on air quality compared to the electric alternatives.

The Corps has therefore determined that there is no practicable alternative to the Stoughton Electric Alternative which would have less adverse impact on the aquatic ecosystem, and also does not have other significant adverse environmental consequences.

4.1 TRANSPORTATION

4.1.1 Introduction

As discussed in Chapter 2, *Project Purpose and Need*, the South Coast Rail alternatives seek to improve public transit service between the South Coast region and Boston, Massachusetts. This improvement would contribute towards meeting the existing and future demand for public transportation between Fall River/New Bedford and Boston and enhance regional mobility. In addition, the South Coast Rail alternatives were developed by MassDOT to be supportive of MassDOT's objective to foster smart growth planning and development strategies in the affected communities.

The transportation chapter provides a regional overview of the transportation conditions in the South Coast region. In addition, this chapter discusses transportation conditions in the vicinity of the proposed alternative corridors and proposed station locations. Grade crossings along the rail corridors associated with the alternatives are analyzed, as well as stations within the alternatives' study corridors.

Section 4.1.2 of this chapter provides an overview of the methodology for analyzing transportation conditions. Section 4.1.3 describes the existing conditions and establishes a basis for projecting future conditions without and with the alternatives (No-Build and Build Alternatives). Direct, indirect, and cumulative effects of the proposed alternatives are analyzed in Section 4.1.4 with respect to ridership demand, quality of service, vehicle miles of travel, regional mobility, traffic operations, grade crossings, and intersection and roadway traffic operations, pedestrian and bicycle accommodations, parking, and public bus transportation at each planned station within the study corridors.

4.1.2 Methodology

Given the transportation focus of the project purpose, the transportation analyses in this chapter, in addition to assessing impacts, also inform the evaluation of the alternatives in meeting the project purpose: "*to more fully meet the existing the future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts to enhance regional mobility*." In addition to analyzing the overall regional transportation conditions, safety and capacity analyses were performed for the regional roadway network, grade crossings for the potential rail corridors were analyzed, and station analyses were performed for each new proposed commuter station. The alternatives station analyses include capacity and safety analyses for the intersections near the proposed stations, traffic signal warrant analyses, and assessments for pedestrians and bicycles, parking, and public transportation. The methodology used for the transportation analyses conforms to the *Guidelines for EIS/EIR Traffic Impact Assessment*[1] and the *2000 Highway Capacity Manual.*[2]

4.1.2.1 Regional Transportation Analysis Methodology

The regional transportation network (both roadways and transit) was evaluated for both existing and future conditions with and without the South Coast Rail alternatives. Future regional transportation conditions were analyzed using four key criteria, which were applied to all alternatives, to assess their performance and impacts on the regional transportation system: ridership, quality of service, vehicle miles traveled (VMT), and regional mobility. This assessment was conducted in a manner compatible

[1] Executive Office of Energy & Environmental Affairs and Executive Office of Transportation and Construction, Guidelines for EIS/EIR Traffic Impact Assessment, July, 1989.

[2] 2000 Highway Capacity Manual, Transportation Research Board, National Research Council, Washington D.C., 2000.

with previous assessment methodologies used during the alternatives analysis process described in Chapter 3, *Alternatives*.

4.1.2.2 Capacity Analysis

The assessment of traffic operations evaluates the operational qualities of the key intersections and roadway sections using the procedures documented in the *2000 Highway Capacity Manual.*[3]

Level of service (LOS) is used to denote the different operating conditions that occur on a roadway segment or at an intersection under various traffic volume loads. It is a qualitative measure of the effect of a number of factors including roadway geometry, speed, travel delay, and freedom to maneuver. LOS provides an index to the operational qualities of a roadway segment or an intersection. LOS designations range from A to F, with LOS A representing the best operating conditions and LOS F representing the worst operating conditions.

LOS designations are reported differently for freeway sections, and signalized and unsignalized intersections. LOS for freeway sections is determined based on speed density and flow rates. For signalized intersections, the analysis considers the operation of each lane or lane group entering the intersection and the LOS designation is for overall conditions at the intersection. For unsignalized intersections, however, the analysis assumes that traffic on the mainline is not affected by traffic on the side streets. The LOS is only determined for left turns from the main street and all movements from the minor street. The overall LOS designation is for the most critical (i.e., worst) minor movement, which is many times the left–turn movement from the side street.

Freeways/Highways

The study methods outlined in Chapter 23 (Basic Freeway Segments) of the *Highway Capacity Manual*[4] (HCM) were used for the LOS analysis of the various freeway and highway segments within the South Coast Rail project study area.

LOS represents reasonable ranges in the three critical flow variables: speed, density of vehicles in the traffic stream, and the flow rate of the vehicles. Basically, as the density of vehicles increases, vehicle speed tends to decrease and the flow rate decreases correspondingly. A freeway can process approximately 2,400 passenger vehicles per lane per hour under <u>optimal</u> conditions (12-foot travel lanes, two-foot median lateral clearance, 6-foot right lane lateral clearance, level terrain, no heavy vehicles, and a driver population consisting of mostly regular users) in rural areas. The freeway capacity drops to about 2,300 passenger vehicles per lane per hour in urban areas. These volumes would result in LOS E operations, the point at which a highway is considered to be operating at capacity. Table 4.1-1 presents these criteria.

[3] 2000 Highway Capacity Manual, Transportation Research Board, National Research Council, Washington D.C., 2000.
[4] 2000 Highway Capacity Manual, Transportation Research Board, National Research Council, Washington D.C., 2000.

Table 4.1-1 Level of Service Criteria–Freeway Sections

Level of Service	Traffic Conditions	Description of Operations
LOS A (best LOS)	Free Flow	Vehicles almost completely unimpeded in their ability to maneuver within the traffic stream.
LOS B	Reasonable Free Flow	The ability to maneuver within the traffic stream is only slightly restricted.
LOS C	Stable Flow	Freedom to maneuver within the traffic stream is noticeably restricted.
LOS D	Approaching Unstable Flow	Freedom to maneuver within the traffic stream is more noticeably limited.
LOS E	Unstable Flow	Operations at capacity. No usable gaps in traffic stream.
LOS F (worst LOS)	Forced or Breakdown Flow	Queues form behind breakdown point and volume-to-capacity ratio exceeds 1.0.

Note: Description based on Association of American State Highway and Transportation Officials and HCM standards.

Once the capacity of a highway is determined, the density can be calculated and the LOS can be determined. The HCM does not recommend a specific LOS for design purposes, but does present a description of the conditions associated with each LOS. The manual describes LOS C as providing for flow with speeds at or near free flow speed; freedom to maneuver within the traffic stream is noticeably restricted; lane changes require additional care and vigilance; and queues may begin to form behind any substantial blockage.

As conditions deteriorate to LOS D, the HCM describes conditions as unstable flow; freedom to maneuver within the traffic stream is more noticeably limited; and a driver experience of reduced physical and psychological comfort levels. The HCM does indicate that the higher the design LOS, the more the highway facility can absorb additional atypical amounts of traffic and still function at a satisfactory level.

Signalized Intersections

Capacity at a signalized intersection is defined for lane groups rather than for approaches or the intersection as a whole. A lane group may be a single movement, a group of movements, or an entire approach, and is defined by the geometry of the intersection and the distribution of movements over the various lanes. Capacity of a lane group is calculated as the maximum rate of flow that may pass through the intersection under prevailing traffic, roadway, and signalization conditions. The rate of flow is generally measured or projected for a 15-minute period and capacity is stated in vehicles per hour. Capacity analysis of signalized intersections involves computing volume–to–capacity (v/c) ratios for each lane group, from which an overall intersection v/c ratio may be derived.

Generally, when two opposing flows are moving during the same signal phase, one of the lane groups will require more green time than the other to process all of its volume. This lane group is defined as the “critical” lane group for the subject signal phase. The concept of a critical v/c ratio is used to evaluate the intersection as a whole, considering only the critical lane groups or those with the greatest demand for green time. Thus, if the green time has not been appropriately allocated to the various approaches, it is possible to have an overall intersection v/c of less than 1.00 (under capacity) but still have individual movements saturated within the signal cycle.

The other major concept in signalized intersection analysis is LOS, which is an index used to grade intersection operations. LOS is defined in terms of delay and ranges from LOS A (free flow conditions) to

LOS F (long delays). Delay represents a measure of driver discomfort, frustration, fuel consumption, and lost time. Specifically, LOS delay criteria are stated in terms of control delay per vehicle during a peak 15–minute period. These criteria are listed in Table 4.1-2.

Table 4.1-2 Level of Service Criteria for Signalized Intersections

Level of Service	Control Delay per Vehicle (sec)[1]
A	<10.0
B	10.1 to 20.0
C	20.1 to 35.0
D	35.1 to 55.0
E	55.1 to 80.0
F	>80.0

Source: HCM, Special Report 209; Transportation Research Board, Washington, DC, 2000.

1 Average control delay per vehicle for a peak 15–minute period.

Delay is a complex measure that depends upon a number of variables such as quality of signal progression, cycle length, allocation of green time, and v/c ratio. Of all the factors cited, v/c ratios have the least effect on delay. Thus, for any given v/c ratio, a range of delay values (and, therefore, LOS) may result. Conversely, for a given LOS, the v/c ratio may lie anywhere within a broad range. The base saturation flow rate used in the signalized intersection analysis model is 1,900 passenger cars per hour of green time per lane. This value is adjusted for prevailing traffic conditions such as lane width, left turns, right turns, heavy vehicles, grades, parking, area type, bus blockage, and left–turn blockage.

Unsignalized Intersections

LOS for unsignalized intersections is based on the assumption that major street traffic is not affected by minor street movements (i.e.; minor street traffic must wait for a gap in major street traffic). The capacity of the intersection to accommodate minor street movements is based on the amount of traffic on the major street and the configuration of the intersection. LOS is based on the average control delay, which is the total elapsed time from the time a vehicle stops at the end of the queue to the time the vehicle departs from the stop line. The average control delay for any particular minor movement is a function of the service rate or capacity of the approach and the degree of saturation. The overall LOS designation is for the most critical (i.e., worst) minor movement, which is often the left–turn movement from the side street. Table 4.1-3 presents these criteria.

Table 4.1-3 Level of Service Criteria for Unsignalized Intersections

Level of service	Control Delay per Vehicle (sec)[1]
A	<10.0
B	10.1 to 15.0
C	15.1 to 25.0
D	25.1 to 35.0
E	35.1 to 50.0
F	>50.0

1 Average control delay per vehicle for a peak 15–minute period.

4.1.2.3 Analysis Approach

The regional highway network is expected to be affected by the No-Build Alternative. The transportation capacity analyses (for the regional network and the proposed stations) are directly related to the projected ridership of the alternatives; therefore, to present the most conservative analysis, the following approach was used to determine the transportation benefits and impacts of the alternatives:

- To conservatively determine the *benefit* of the alternatives on the regional highway network, the Build Alternative with the lowest projected ridership analyzed in the DEIS (Rapid Bus Alternative[5]) was used since it would shift the fewest automobile users from a highway to a transit trip. While the Rapid Bus Alternative has been eliminated in the FEIS, it remains the most appropriate Build Alternative for analyzing the impacts on the regional highway network due to its low projected ridership, and maintains a conservative approach consistent with the DEIS. Although not specifically analyzed, the Stoughton and Whittenton Alternatives (both electric and diesel variants) would result in proportionally greater benefits to the regional highway system.

- Conversely, the Build Alternative with the highest projected ridership at each station was used to evaluate the impacts in the areas around proposed station locations. For station locations shared between alternatives, separate intersection analyses were not conducted for each alternative, because the lower projected ridership for these alternatives would result in equal or less impact than the analysis using the highest ridership.

To maintain a conservative approach consistent with the DEIS/DEIR, a specific Build Alternative was used for the analysis of each transportation study area. In some cases, Build Alternatives that have been eliminated from further consideration in the FEIS/FEIR were used as the basis for the transportation impact assessment. This approach is reasonable because the alternatives used in the analysis remain the most conservative in terms of estimating regional traffic benefits (alternative with lowest ridership) and station area traffic impacts (alternative with highest ridership). The following identifies the Build Alternative used for analysis of the various transportation study areas:

[5] As discussed in Chapter 3, the Rapid Bus Alternative evaluated in the DEIS/DEIR was eliminated from further consideration. However, the regional highway benefits assessment based on the Rapid Bus Alternative is retained in the FEIS/FEIR because it provides a conservative assessment of the regional highway benefits of the Stoughton and Whittenton Alternatives.

- The electric rail alternatives were analyzed because projected ridership is equal to or higher than projected ridership on the corresponding diesel alternative.
- Regional highway network (sections of Route 140, Route 24 and I-93)—Rapid Bus Alternative. The Rapid Bus Alternative has been eliminated from further consideration, but provides a conservative basis for evaluating the regional traffic benefits of the Stoughton and Whittenton Alternatives.
- King's Highway Station—Attleboro Electric. The Attleboro Electric Alternative has been eliminated from further consideration, but provides a conservative basis for evaluating station area traffic impacts because it had the highest ridership projection for this station of all the Build Alternatives.
- Whale's Tooth Station—Attleboro Electric. The Attleboro Electric Alternative has been eliminated from further consideration, but provides a conservative basis for evaluating station area traffic impacts because it had the highest ridership projection for this station of all the Build Alternatives.
- Freetown Station—Stoughton Electric
- Battleship Cove—Attleboro Electric. The Attleboro Electric Alternative has been eliminated from further consideration, but provides a conservative basis for evaluating station area traffic impacts because it had the highest ridership projection for this station of all the Build Alternatives.
- Fall River Depot—Attleboro Electric. The Attleboro Electric Alternative has been eliminated from further consideration, but provides a conservative basis for evaluating station area traffic impacts because it had the highest ridership projection for this station of all the Build Alternatives.
- Taunton Depot—Stoughton Electric
- Easton Village—Stoughton Electric
- North Easton—Stoughton Electric
- Taunton Station (Stoughton Alternatives Only)—Stoughton Electric
- Raynham Park Station—Whittenton Electric
- Stoughton Station (relocation)—Stoughton Electric
- Dana St. Station (Whittenton Alternatives only)—Whittenton Electric

Since there is only one set of transportation analyses for each station (worst case scenario), the results of the analyses are presented by community.

The methodology used in this chapter is standard transportation planning industry practice for the evaluation of transportation systems and infrastructure. Much of the evaluation was based on a 2030

traffic forecast with and without the Build Alternatives provided by the Central Transportation Planning Staff (CTPS) for the DEIS/DEIR. Certain key indicators such as ridership and VMT have been updated in the FEIS/FEIR for a 2035 traffic forecast. As discussed further below, the 2035 ridership analysis update results were also used to review and update the station-level traffic impact assessment where appropriate.

4.1.2.4 Traffic Growth Forecast

CTPS is the staff for the metropolitan planning organization (MPO) for the Boston region and works with the communities within the region to address issues such as transportation, land use, and economic development. The Boston Region Metropolitan Planning Organization (MPO) is responsible for conducting the federally required metropolitan transportation-planning process, and allocating federal and state transportation funds to programs and projects in the Boston metropolitan area. The MPO and CTPS function independently of MassDOT, and their activities are periodically reviewed by both the Federal Highway Administration and Federal Transit Administration.[6] MassDOT provided funding to CTPS to conduct the transportation modeling analyses for the South Coast Rail project.

The CTPS regional travel demand model was used to provide the traffic forecasts for the entire study area. This model is run using Emme software. CTPS's method of travel demand forecasting follows the traditional four steps of trip generation, trip distribution, modal split, and travel assignment. The model uses changes in population, number of households, employed residents, number of automobiles, and total employment to forecast changes in traffic over time.

Using the future No-Build model output, No-Build weekday morning and evening peak hour turning movement volume networks were created. For each municipality, a background growth rate was established based on model outputs. Table 4.1-4 shows the background traffic growth rate used in each community. These growth rates were applied to the existing traffic volumes to develop 2030 No-Build volumes. Traffic increases from specific development projects that were not included in the model were also added to the network to develop the final No-Build networks for local intersections.

Table 4.1-4 Background Traffic Growth Rate (by Community)

Community	Growth Rate[1]
New Bedford	4.1 %
Fall River	7.1 %
Freetown	18.4 %
Taunton	4.7 %
Norton	9.4 %
Raynham	8.1 %
Easton	6.9 %
Stoughton	5.0%

1 Total (aggregate) growth rate used to convert 2008 conditions to 2030 conditions

Source: CTPS Travel Demand Model.

A similar process was used to project 2030 No-Build traffic volumes on Route 24. A background growth rate was developed for each direction in each peak hour for each segment. As with local intersections, traffic from specific developments not included in the traffic model were added. Appendix 4.1–A

6 Boston Region Metropolitan Planning Organization. About the MPO. http://www.ctps.org/Drupal/mpo

provides specific information regarding the overall growth on each segment by direction and time of day.

No-Build Analysis

In order to evaluate access for the bus park-and-ride locations under future No-Build conditions with enhanced bus service, intersection capacity analyses were performed at park-and-ride driveway locations using 2030 projected traffic volumes. Traffic volumes for the 2030 design year were projected based on additional vehicle trips associated with the increased bus ridership projections provided by CTPS.

The resulting peak hour volumes were analyzed to evaluate how well the future infrastructure will accommodate the demands placed on it during the morning and evening peak hours. The analysis produces a LOS rating for each facility. The criteria for determining LOS at signalized and unsignalized intersections and on freeway sections is described above.

Station Area Analysis Methodology

Traffic Demand

Traffic demand estimated for the alternatives are based on the 2030 and 2035 ridership forecasts developed by the CTPS (see Appendix 3.2-H (2035) and Appendix 4.1-H (2030)). CTPS developed these forecasts based on a number of variables, such as observed commuter rail ridership in similar areas, magnitude of service to be provided, and future estimates of population and employment within the South Coast region and greater Boston area. All of these data were analyzed via a regional travel demand model, which ultimately provided a future ridership estimate for the proposed service. The basis for the model is documented in Appendix 3.2-G.

For the DEIS/DEIR, CTPS conducted 2030 Build model runs for each alternative by including the new bus or rail service as a travel option. The model was used to quantify the number of vehicle trips diverted from regional roadways to local roadways because of drivers and riders who change mode from passenger car to transit service. Trip generation for each station was based on projected park-and-ride (i.e., driving and parking at the station) and drop-off (i.e., being dropped off or picked up by another driver) ridership. The analyses of impacts on traffic operations are based on the peak hour park-and-ride and drop-off ridership projections for each station. The park-and-ride ridership was divided by a vehicle occupancy rate (VOR) of 1.05 to calculate the number of park-and-ride vehicles entering and exiting the stations. Two vehicle trips were assumed for each drop-off rider: one entering and one exiting the proposed station. The same basic methodology was used for the 2035 ridership forecasts (see the CTPS memorandum provided in Appendix 3.2-H).

Using the Build model outputs, peak hour turning movement volume networks were developed for each Build Alternative. The rail related trips were distributed as new traffic and assigned to the roadway network based on the distribution of trips from the travel demand model. To present a conservative analysis condition, no adjustments were made to the traffic volumes to account for diverted trips within the local street network. The peak hour volumes were then used to conduct LOS assessments for the Build Alternatives. When compared to the No-Build Alternative, the LOS assessment for the Build Alternatives will show the effect of the proposed action on transportation conditions.

Where impacts could not be avoided or minimized, mitigation was proposed and evaluated for effectiveness. Mitigation was proposed for intersections where LOS E/F conditions result because of the Build Alternatives and where LOS E/F conditions under the No-Build Alternative are notably worsened with the Build Alternatives (generally an increase in control delay of more than 10 seconds).

Safety Analysis

In order to identify crash trends, historical crash data were obtained from MassDOT Highway Division for each community for the most recent three-year period available at the time of the analysis. For each proposed station site, vehicle crashes were compiled by roadway and key intersection. Specific crash characteristics include year of crash, crash type, severity, weather, and time of day.

Crash rates are calculated based on the number of crashes at an intersection (i.e., crash frequency) and the volume of traffic traveling through the intersection (i.e., vehicle exposure) on an annual daily basis[7]. Rates that exceed the MassDOT Highway Division district or statewide average (i.e., arithmetic mean) could indicate safety or geometric issues at an intersection. The South Coast communities are location in District 5 of the MassDOT Highway Division. The District 5 average crash rate for unsignalized intersections is 0.59 crashes per million entering miles and the rate for signalized intersections is 0.84 crashes per million entering miles. The statewide crash rate is 0.66 for unsignalized intersections and 0.87 for signalized intersections.

Documentation of the crash data and crash rates is provided in Appendix 4.1- B.

Grade Crossings

An inventory of highway-railroad at-grade crossings was performed in November and December of 2008 to identify and document existing active (with freight activity) and inactive grade crossings along the following rail corridors.

- New Bedford Main Line—Cotley Junction to State Pier in New Bedford
- Fall River Secondary—Myricks Junction to Battleship Cove in Fall River
- Attleboro Secondary—portion in Taunton utilized by Whittenton Alternatives
- Stoughton Line—Canton Junction to Cotley Junction
- Whittenton Branch—Stoughton Line to Attleboro Secondary

The active rail crossings located along the Northeast Corridor were not included in the inventory. Those crossings are part of the current operating railroad and would not be altered under this project.

The existing conditions of each crossing were evaluated to determine the crossing geometry, sight distances, and roadway traffic patterns. Each rail and roadway approach was photographed and sketches were prepared to illustrate the warning systems in place and other physical features that will have to be considered during the layout and design of the proposed grade crossing.

[7] Statewide average crash rates reflect the average of crash rates contained in a database of signalized and unsignalized intersection crash rates compiled by MassDOT Highway Division, calculated for both signalized and unsignalized locations. MassDOT Crash Rate Information. 2012. http://www.mhd.state.ma.us/default.asp?pgid=content/traffic/crashRateInfo&sid=about.

Grade Crossing Incident Prediction Analysis Methodology—A highway/rail incident, as defined by the Federal Railroad Administration (FRA), is any impact between a rail and highway user at a crossing site, regardless of severity. This includes motor vehicles and other highway / roadway/ sidewalk users at both public and private crossings. From 2002 to 2011 for the 333 active at-grade crossings the MBTA operates, an average of three incidents occurred per year (0.99 incidents per million train miles). In comparison, the national average is 72 incidents per year or 1.57 incidents per million train miles.

In order to establish what may be the incident rate for future conditions, the FRA's Office of Safety Analysis has developed a Web Accident Prediction System (WBAPS), which is used to calculate the probability that an incident will occur in any given year. This system generates incident reports for public highway/rail intersections for a state, county, city, or railroad and ranks them by predicted collisions per year. A train incident is defined by the FRA as an event involving on-track rail equipment that results in monetary damage to the equipment and track above a certain threshold. Incident predictions are based on a current inventory of at-grade crossings and collisions from 2002 to 2011. Using the WBAPS, incident predictions were calculated for each town along the South Coast Rail project and compared to similar rates estimated for the entire MBTA system.

Gate Closure

The impact of the grade crossings on traffic operations requires the calculation of the amount of time the roadway would be blocked. In accordance with standard practice, it is assumed that the gate system would close 30 seconds prior to the train's arrival at the grade crossing and for 15 seconds after the train clears the crossing. This time is estimated by dividing the approximate length of the train by the approximate speed of the slowest train expected at that crossing. In most cases where the rail crossing is perpendicular to the roadway, the sum of these components yields the total time (60 seconds) that the roadway is blocked. A 70 second gate delay time was used for unusually wide or skewed crossings.

For crossings that are located within 500 feet of a station platform, the gates would operate differently depending on the direction of travel. The delay for a train passing through the crossing before stopping at the station would be 60 seconds, as defined above. However, as a safety measure, the gates must also be activated as a train pulls into a station prior to reaching the crossing. The train then stops at the station to drop off or pick up passengers and then continues through the crossing. The timing for this situation was determined based on:

- As the approaching train is detected, the gates would close.
- When the train stops at the platform the gates would open.
- The gates close again as the train leaves the station (it is estimated that approximately four cars would be able to clear the crossing while the train dwells in the station).
- After the train passes through the crossing the gates reopen a final time.

The total gate delay time is estimated to be 150 seconds. Since this time also includes station dwell time, the projected delays and queues were reduced to reflect the estimated four cars that would clear the crossing during the station dwell time.

Determination of Vehicle Volumes

Where available, existing traffic volume data at grade crossing locations were obtained from the MassDOT Highway Division. These data were supplemented by counts collected as part of the traffic analysis for the proposed project. The 2030 morning and evening peak hour traffic volumes were developed for each grade crossing by applying the annual growth rates obtained from the CTPS regional transportation demand model.

Traffic Queue and Delay Calculation

The peak direction traffic volumes were converted to an average arrival rate by dividing the hourly volume by the number of seconds in an hour (3,600). By applying the arrival rate to the total time that the roadway was blocked, an average queue estimate was developed. Assuming a random arrival of vehicles at the crossing, the average delay per stopped vehicle was estimated based on gate closure time plus the startup time for the vehicles in the queue. An average start up time of two seconds was used, representing a four second start up time for vehicles in the beginning of the queue and zero seconds toward the back of the queue. The average delay is therefore equal to one-half of the time that the roadway is blocked plus two seconds per vehicle for one-half of the average queue.

Determination of Impact

After the average queue was calculated, impacts of the queue on nearby intersections were determined. A value in the range of 20 to 25 feet per vehicle is generally used to estimate the length of queues. This length includes the length of the vehicle and the spacing between queued vehicles. For this analysis, the total number of vehicles was multiplied by 25 feet per vehicle to determine the total average length (in feet) of the queue.

Inactive or Abandoned Railroad Rights of Way

In locations where reactivation of inactive or abandoned railroad rights-of-way are proposed, the analysis provided includes more detail with respect to traffic flows and average delays. This is necessary to determine the projected impacts of gate closures due to the absence of physical gate closure data.

4.1.2.5 Stations

As shown in Figure 1.4-1, the commuter rail alternatives include potential commuter rail stations within New Bedford, Freetown, Fall River, Taunton, Easton, Stoughton, and Raynham. Intersections within the seven communities were selected for safety and traffic operation analyses based on the proposed locations of the new or relocated commuter rail stations.

Since boardings at existing commuter rail stations located near the end of the existing Stoughton Commuter Rail Line are not expected to increase as a consequence of the alternatives, no traffic analyses, beyond the identification of new grade crossing locations, were completed for existing stations or municipalities with existing stations.

Roadway and Intersection Inventory

A comprehensive field inventory of major roadways and key intersections was completed for each commuter rail station study area. Field reconnaissance included an inventory of roadway geometry, observed vehicle speeds, signalization (where applicable), other traffic control, and nearby land uses. Documentation of the intersection inventory field work is provided in Appendix 4.1-C. Detailed roadway and intersection descriptions are provided in Appendix 4.1-D.

Traffic Volume Data Collection

Traffic volume data were collected in September and October 2008 for roadways and critical intersections serving each of the proposed rail stations. This data included automatic traffic recorder (ATR) counts and manual turning movement counts (TMCs). ATRs were collected along major roadways to provide an understanding of daily and peak hour traffic flows in the vicinity of each potential commuter rail station site. Two–hour TMCs were conducted at key intersections during the weekday morning and evening commuter peak periods. Vehicles, bicycles, and pedestrians were counted. All TMCs were conducted midweek (Tuesday through Thursday) to capture traffic count data that depict typical weekday peak conditions. The TMCs were balanced, and rounded to form the traffic volume networks used to evaluate existing traffic operations. To determine whether or not it was necessary to seasonally adjust the recorded traffic volumes, historical traffic count data from the following MassDOT Highway Division permanent count stations were reviewed:

- Randolph, Route 24 south of I-93
- Raynham, I–495 north of Route 24
- Raynham, I–495 south of Route 24
- Freetown, Route 140 at the New Bedford city line
- Taunton, Route 24 north of Route 140
- Fall River, I-195 west of Route 24

Based on observed data from these locations, traffic volumes for September and October are generally 1 to 8 percent higher than the yearly average. Consequently, the actual traffic counts were not adjusted to reflect any seasonal difference in traffic volumes; and therefore represent a slightly higher than average condition.

Documentation of the traffic volume data collection is provided in Appendix 4.1-E.

Traffic Signal Warrant Analysis

The Manual of Uniform Traffic Control Devices (MUTCD) defines a traffic signal warrant analysis as an engineering study of traffic conditions, pedestrian characteristics, and physical characteristics of an intersection performed to determine whether installation of a traffic control signal is justified at a particular location. The study includes an analysis of factors related to the existing operation and safety at the intersection in question, the potential to improve these conditions, and standard criteria which could necessitate the installation of a traffic signal, known as "warrants." The satisfaction of a traffic signal warrant or warrants shall not in itself require the installation of a traffic control signal.[8]

Peak hour signal warrant analyses were conducted at study area intersections in conformance with the MUTCD[9] standards. For the purposes of this analysis, peak hour traffic signal warrants were evaluated for unsignalized intersections that exhibit poor traffic operations and would decline further as a result of the proposed project. If an unsignalized intersection does not meet the peak hour traffic signal warrant

[8] Chapter 4C. Traffic Control Signal Needs Studies. Manual of Uniform Traffic Control Devices (MUTCD) Federal Highway Administration Washington, DC 2003.

[9] Manual of Uniform Traffic Control Devices (MUTCD) Federal Highway Administration Washington, DC 2003.

based on projected 2030 traffic volumes, no additional analysis would be necessary. All site driveway locations were also evaluated for traffic signal installation.

Locations meeting traffic signal warrants under the peak condition would be evaluated for four and eight-hour traffic signal warrants as part of the preliminary design process. Meeting a traffic signal warrant indicates that a traffic signal could be placed at a particular location; however, satisfaction of a traffic signal warrant does not in itself require a traffic signal be installed. Locations where traffic signal installation is considered an appropriate mitigation measure are discussed later in this section. Documentation of the preliminary traffic signal warrant analysis is provided in Appendix 4.1-F.

Pedestrians and Bicycles

The travel demand model was also used to project total pedestrian and bicycle volume at each planned station for the Build Alternatives. For each transportation analysis zone (TAZ) within the regional model, CTPS provided the number of pedestrians and bicyclists using transit and the specific station they would access. The pathways of travel between zones and each station were mapped and pedestrians and bicyclists were assigned to routes accordingly. Bicycle accommodations were evaluated qualitatively for the Build Alternatives with respect to their ability to serve projected users and any projected impacts from project related traffic and planned or proposed roadway improvements. Pedestrian/bicycle volume networks for all alternatives can be found in Appendix 4.1-G.

Parking

The parking assessment for stations associated with the alternatives compares the planned number of parking spaces to the projected peak parking demand and identifies any existing parking supply that may be affected by the proposed project. Peak parking demand at each station was projected based on the daily passenger boardings determined by the CTPS travel demand model. For the purposes of this analysis the peak parking demand is equal to the number of passengers who would drive and park at the station prior to boarding the train. No reduction in parking demand was taken in order to account for carpooling. Locations where projected demand for parking exceeded the planned parking supply were identified. There were no parking demand analyses of the Battleship Cove and Easton Village stations because no parking is planned for either location.

The existing parking supply in the vicinity of each proposed station location was qualitatively evaluated in order to determine whether any existing parking is vulnerable to impacts due to the proposed project. Areas that have potential vulnerability have been identified and steps to mitigate impacts noted if applicable.

Public Bus Transportation

Existing bus services near the planned stations were reviewed to determine if route or service adjustments could be made to provide good connections between local transit services and commuter rail service. Using the CTPS travel demand model, potential bus route adjustments to provide direct service to planned stations were evaluated. Limited bus transit activity is anticipated at most stations. More substantial bus activity is projected at the Whale's Tooth station due to proximity to regional bus transit hubs. Trip generation characteristics for this station are provided in Appendix 3.2-H.

4.1.3 Existing Conditions

This section presents the Affected Environment (Existing Transportation Conditions) for the South Coast Rail project. An overview of the South Coast region, including ridership demand, quality of service, vehicle miles of travel, and regional mobility is presented. In addition, existing traffic operations were analyzed for the highways and intersections within the South Coast region, existing grade crossings for the proposed rail corridors are identified, and proposed stations are analyzed. The existing station analyses include an inventory of roadways and intersections, existing traffic volumes, crash analysis summary, and traffic operations analysis.

4.1.3.1 Regional Overview

Quality of Service

The existing transportation system serving the South Coast region has inadequate capacity, leading to lack of regional mobility, between the South Coast region and Downtown Boston and within the South Coast region itself. This is due in part to the relative lack of public transit connections between New Bedford/Fall River and Boston and between South Coast cities (New Bedford, Fall River, Taunton and others).

In this regard the South Coast region is severely underserved relative to other regions. This is partially due to the absence of commuter rail, which in other regions provides intra (within) regional connectivity (mobility), partially as a byproduct of interregional connectivity with Boston.

The inadequacy of public transit service in the South Coast region is reflected in several aspects. The availability of public transit service in absolute terms and compared to other regions (especially those that have a large commuting segment to downtown Boston) is limited, and the quality of transit service as expressed in travel time and frequency of service is poor, especially during the peak hours. The geographic availability of transit service to people in the region is also relevant in terms of access to employment opportunities and services, including education and healthcare. In addition to transit services between the South Coast region and Boston, transit services within the South Coast region are also relevant. An indicator of quality of transit service is the MBTA's Service Delivery Policy.[10] This policy identifies minimum frequency of service levels that provides the guidelines by which the MBTA maintains accessibility to the transportation network within a reasonable waiting period. The minimum frequency of service standards is the minimum frequency that must be maintained in a service. For commuter rail and commuter bus minimum frequencies should provide three trips in a peak direction during the AM and PM peak periods.

Existing transportation in the South Coast region is predominantly auto-oriented and transit services within the South Coast region are limited to bus and demand-response services operated by regional transit authorities and private carriers. Most of the commuter trips from the South Coast region to the Boston market are in single occupant vehicles. Public transit accounts for a minor proportion of work trips in the service area. To a large extent, this can be attributed to the lack of public transit alternatives other than privately-operated bus service. As discussed below, many communities in the South Coast region lack public transit facilities other than private bus services and major population centers are as

[10] MBTA's Transit Service Policy is similar to other service delivery policies and standards from regional transit agencies, such as Los Angeles County MTA, Detroit DOT, Washington, D.C. MTA, Chicago Transit Authority, and others.

much as 25 miles from existing commuter rail stations. All commuter rail stations are located outside the South Coast region and are approaching capacity.

Bus Service

Local bus public transit within the South Coast region is provided in Taunton by Greater Attleboro Taunton Regional Transit Authority (GATRA) and in New Bedford and Fall River by Southeastern Regional Transportation Authority (SRTA). GATRA also operates intercity bus service between Taunton and Providence, Rhode Island.

Bus service to Boston from the South Coast region including the cities of New Bedford, Fall River, and Taunton is limited to private carriers (Figure 2.2-1). Private carriers also connect New Bedford, Fall River, and Taunton with each other and with Providence, Newport and points beyond. Bus service from the South Coast region to Boston uses the regional roadway system and is therefore subject to the same congestion and safety problems on the highway system as other vehicles, resulting in long and unpredictable travel times. The existing bus service between the South Coast region and Boston fails the MBTA's Service Delivery Policy. The bus service is also substantially more expensive than MBTA commuter rail services over similar distances, creating an additional constraint on usage of bus service, especially for lower income groups. Some bus service exists to commuter rail stations outside the South Coast region; however the transfer between two transit services increases overall travel cost and overall travel time, rendering it less attractive.

In addition, existing express bus services within the South Coast region are limited to a few stops in order to realize a total travel time competitive with automobiles. Serving additional communities with these bus services would substantially slow service to unacceptable levels, which would result in fewer riders. The second constraint that limits intraregional connections is bus capacity. In order to attract riders, existing bus services seek to minimize headway (maximize frequency) while operating at or near capacity almost from their initial point of departure, with very limited or no intermediate stops within the South Coast region. Existing bus services thus operate as exclusive routes with few in-between stops and thus do not provide substantial interregional connectivity.

While the current bus service plays an important role, especially as it is the only regular transit service between the South Coast region and Boston, its use is limited, reflecting constraints related to travel time, and service frequency.

Vanpools/Carpools

Vanpools in communities of the South Coast region are provided through MassRides, a program of MassDOT. Although relevant as a complementary service vanpool and carpool travel times are severely impacted by slow travel speeds on the expressway and secondary roads.

Park-and-Ride

Park-and-ride facilities and carpool/vanpool services are offered along the primary regional travel corridors in the South Coast region. Park-and-ride lots are associated with car-pooling, van-pooling, or private bus service to Boston. There are nine public park-and-ride lots located in the South Coast region, as illustrated in Figure 4.1-1, of which five are located along the primary roadways from the region to the Boston metropolitan area and four not in the immediate vicinity of the primary access routes to Boston. In addition, three private park-and-ride lots in the South Coast region are available exclusively

for customers using the private bus services to Boston. Three public park-and-ride lots are outside the South Coast region, but still along the Route 24 access corridor to Boston. Park-and-ride facilities as feeders for bus and car-pooling and van-pooling services are limited in their effectiveness as a transportation connection with Boston, due to the inconvenience of transfers and travel times associated with the congested roadway system, both in terms of traveling to the park-and-ride facility and travel from the park-and-ride facility to Boston.

Commuter Rail

Many communities within the South Coast Rail study area do not currently have commuter rail service. The nearest commuter lines (MBTA's Providence Line and Middleborough Lines) terminate on the northwest and northeast edges of the South Coast region. Starting in May 2013, MBTA, in cooperation with the Cape Cod Regional Transit Authority, established a seasonal weekends-only service known as the Cape Flyer, extending the Middleborough line from its current terminus in Middleborough to Hyannis. However, this service is limited to three round-trips per week, all on weekends, and thus serves weekend tourists rather than daily commuters between Boston and the South Coast. In fact, the three major cities in the South Coast region; Taunton, Fall River, and New Bedford are the only cities within 50 miles of Boston that are not served by passenger rail. The closest commuter rail stations are Middleborough/Lakeville (MBTA Middleborough Line), and Attleboro Station and Providence Station (MBTA Providence Line). The Middleborough Line serves areas east of the South Coast region and southeast of Boston, with stations in Lakeville and Bridgewater, while the Attleboro/Providence and Stoughton Lines serve communities to the north and west of the South Coast region. The Attleboro and Mansfield Stations are the primary access points on the Attleboro/Providence Line. The Stoughton Station serves as the primary access point on the Stoughton Line. All of the communities in the heart of the South Coast region, are outside a 6-mile access radius of these stations, and some, including the major population centers such as New Bedford and Fall River (combined population approximately 182,000), are more than 20 miles and up to 25 miles from the nearest train station. Due to their distance to the nearest commuter rail station the existing commuter rail lines to Boston are difficult for residents to access, especially for those living in Taunton, Berkley, Freetown, Fall River, and New Bedford. Travel to these stations is also limited to local secondary roads, which further increases travel time.

For those commuters in the South Coast region who live closer to commuter rail stations outside the South Coast region, constraints to the usage of the existing stations are posed by station parking and system capacity issues, as exemplified by the seat utilization ratio on the Providence line in Table 4.1-5. Commuter rail services are currently approaching or over capacity and system capacity is limited by parking capacity at these stations. Commuter rail parking lots in Attleboro, Mansfield, and to a lesser degree in Stoughton are already heavily utilized, as shown in Table 4.1-6 and are not positioned either within the regional road network or within their local (developed) context to handle projected future growth. In addition, some peak hour trains already experience heavy passenger loads, which was especially evident before the recent economic downturn. Therefore, the existing commuter rail service, although within reach of some communities in the South Coast region, is not sufficient to handle the anticipated growth in ridership.

Table 4.1-5 Ridership on Providence and Stoughton Lines

Line	AM Peak Passengers	AM Peak Seating Capacity	AM Peak Seat Utilization*
Providence	11,017	8,532	129%
Stoughton	2,771	3,558	78%

Sources: MBCR Ride Check December 2006, MBTA South Side Equipment Schedule
* Assumes all passengers continue to South Station, Stoughton and Providence/Stoughton Lines.

Table 4.1-6 Parking Utilization at Providence and Stoughton Lines Stations

Station	Occupied Spaces	Total Spaces	Utilization
Providence Line+			
Providence	N/A	330	N/A
South Attleboro	918	992	93%
Attleboro	756	770	98%
Mansfield	812	805	101%
*Stoughton Line**			
Stoughton	350	441	79%

\+ MBTA, 2000
* OCPC 2004

In summary, commuter rail service currently does not extend into the South Coast region, making access to commuter rail difficult for area residents. The relatively small ridership share of South Coast commuters using commuter rail services terminating outside the South Coast region is low, which reflects the constraints associated with this service for South Coast region commutes to Boston.

Vehicle Miles Traveled

VMT measures the extent of motor vehicle operation or the total number of vehicle miles traveled within the study area on given day. It is an important gauge for air quality and greenhouse gas emissions, as emissions of air pollutants and greenhouse gases are related to the distance traveled by automobiles (and to a lesser degree congestion). Daily regional automobile VMT is expected to grow from 109,926,000 under existing conditions to 118,894,000 by 2035 under the No-Build Alternative (based on updated modeling conducted by CTPS in 2012, see Appendix 3.2-H).

Regional Mobility

In addition to the lack of one-seat transit rides from one municipality to another within the South Coast region and adjoining regions, the lack of regional mobility is reflected by poor connectivity between the South Coast region and Boston.

The current transportation system serving the South Coast region is primarily a highway system composed of major, limited access state routes, regional highways, and local roadways (Figure 1.2-1). There are five major highways in the South Coast Rail project study area providing the primary access within and to adjacent regions:

Route 24 is the main north-south highway between the South Coast region and the metropolitan Boston area. This limited access facility begins at the Rhode Island state line at Tiverton, connects with I-195 on

the east side of Fall River, and terminates at I-93/Route 128. It passes through Fall River, Freetown, Berkley, Taunton, and Raynham within the projects' study area.

Route 140 is a limited access highway connecting New Bedford and Taunton. It passes through the South Coast region communities of New Bedford, Freetown, Lakeville, and Taunton. The limited access portion of Route 140 ends at Route 24 in Taunton, providing an important link between the South Coast cities and towns of New Bedford, Dartmouth, Mattapoisett, Acushnet, and Taunton. Route 140 continues north from Taunton, roughly paralleling I-495, but not as a limited access facility.

Route 79 is a limited access segment approximately 4 miles long, beginning at I-195 on the west side of downtown Fall River and ending at Route 24 in northern Fall River. Route 79 provides a link from downtown Fall River and the communities located along I-195 west of Fall River to Route 24.

Route 138 is primarily a two-lane facility that passes through the South Coast region communities of Fall River, Somerset, Dighton, and Taunton, and provides access north to Raynham, Easton, and Stoughton. It connects with I-195 and the limited access segment of Route 79 in Fall River, the non-access controlled section of Route 140 in Taunton, and I-495. Route 138 also provides access to the MBTA's existing Stoughton station and planned stations in Easton and Raynham.

I-495 is a circumferential highway around metropolitan Boston that runs primarily northwest/southeast in the South Coast region, linking Route 24 to the I-90 and I-95 corridors. This facility provides access for a portion of the region to MBTA commuter rail stations in Middleborough/Lakeville and Mansfield. I-495 passes through Wareham, Rochester, Middleborough, Raynham, Taunton, and Norton, connecting with I-95 near the Mansfield/Foxborough line and Route 24 in Raynham.

Traffic generated within the South Coast region must travel on I-93/Route 128 and I-93/Route 3 (Southeast Expressway) to reach downtown Boston. Route 128 is Boston's inner circumferential highway that provides access to much of the metropolitan Boston region. Following I-93 north/Route 128 south from Route 24 leads to I-93/Route 3 (Southeast Expressway) and downtown Boston, approximately 8 miles from the I-93/Route 128/Route 3 interchange in Braintree. Following I-93 south/Route 128 north from Route 24 leads to I-95 approximately 3 miles to the north, and to I-90 approximately 15 miles to the north. I-90 (Massachusetts Turnpike) provides the only limited-access highway to Boston from west of the city. Route 128 and the Southeast Expressway are heavily congested roadways, particularly during peak periods.

Traffic volumes on Route 128 are approximately 135,000 vehicles per day north of Route 24 (towards I-95) and 167,000 vehicles per day to the south (towards I-93/Route 3). I-93/Route 128 provides four general purpose travel lanes in each direction between Route 24 and I-93/Route 3. North of the I-93/Route 3 interchange in Braintree, four general-access lanes and one high occupancy vehicle (HOV) lane in the peak direction and three general access lanes in the non-peak direction are provided during peak periods. During off-peak periods, the roadway provides four lanes in each direction through Southampton Street Massachusetts Highway Department operates HOV lanes on I-93/Route 3 from just south of the Furnace Brook Parkway exit in Quincy to the Columbia Road exit in Dorchester. As of 2009, the HOV lanes are open to all two-person carpools. Traffic volumes on I-93/Route 3 are as high as approximately 191,000 vehicles per day.

Freight Operations

The existing freight service for the South Coast region is shared between Mass Coastal and CSX. CSX dispatches several lines from its Selkirk, New York control office. The MBTA transferred dispatching of the Middleborough Secondary to CSX in 2009. There are several secondary tracks referred to as the Framingham (portion of track from Framingham to Mansfield), Attleboro (area of track from Attleboro side track to Cotley Junction), and the Middleborough (from Cotley Junction to the Middleborough branch of the Old Colony Railroad), as well as the New Bedford and Fall River branches.

CSX transferred ownership of the Fall River Secondary and New Bedford Main Line to MassDOT in June 2010. CSX simultaneously transferred the freight operating rights along these corridors to Mass Coastal. Currently, the existing freight service for the Fall River Secondary and New Bedford Main Line is therefore owned by the Commonwealth of Massachusetts and operated by Mass Coastal, while the Attleboro Secondary is owned by the Commonwealth of Massachusetts and operated by CSX. Freight service operates at maximum authorized speed of 40 mph with multiple civil and operational speed restrictions. All operations on these secondaries are under Dark Territory Control (no vital wayside signaling system). Figure 1.2-1 shows the existing rail transportation system, and Figure 3.2-10 shows the ownership of the rail segments.

CSX Freight Operations

The existing long haul freight service in this region is provided by CSX. CSX runs a late night/early morning train from Framingham to Attleboro where the train makes a run-around (reversing) operation and heads North on the NEC to Canton Junction (if warranted by customer demands) or east towards Cotley Junction to exchange cars with Mass Coastal. The train then continues on to Middleborough, exchanging cars with CSX local trains at Middleborough Junction. During this operation the Middleborough Secondary is often impeded as CSX uses the secondary as a switching lead, a track used by the switch engine while sorting railcars that gives it room to pull back while switching.

Additionally, CSX runs a freight train north to exchange cars with the Fore River Railroad at Greenbush Junction as well as to service sidings along the Middleborough branch of the OCRR. This movement occurs once per weekday between Braintree and Middleborough.

CSX runs this train during daylight hours in response to community concerns. This constrained operation is very difficult to complete at times trying to fit switching operations in small windows so as not to conflict with the MBTA passenger service.

Mass Coastal Freight Operations

Locally in the South Coast Region, Mass Coastal services both the New Bedford Mainline and the Fall River Secondary from the Cotley siding track north of Cotley Junction, where it interchanges with CSX for the South Coast Region. New Bedford is serviced 2 days per week, except during “sludge season,” when it is serviced three times per week, typically Tuesdays and Thursdays. “sludge season” refers to annual dredging in the New Bedford Harbor, the duration of which varies from year to year.[11] Fall River is serviced three days per week, typically Mondays, Wednesdays, and Fridays. According to Mass Coastal, the dredging activities in New Bedford require few, if any, additional trains. The tracks from Cotley and

[11] The “sludge season,” refers to the USEPA’s dredging project in New Bedford Harbor. According to the Water Quality Monitoring Summary Reports prepared for the USACE, the dredging seasons in 2010 through 2012 went from June to September.

Myricks Junctions southward are in poor shape, and Mass Coastal trains are typically unable to safely operate at speeds exceeding 10 mph.

Freight activity on the New Bedford Mainline track includes the Watuppa Line, which runs east/west between New Bedford and Westport. Approximately half of the Watuppa Line is owned by Bay Colony Railroad and the other half by MassDOT (currently operated by Bay Colony Railroad for Mass Coastal). The interchange point for Bay Colony and Mass Coastal is at the Watuppa Wye between Nash Road and Deane Street in New Bedford.

The majority of the existing freight traffic on the Fall River line is from/to Wharf Yard at Battleship Cove.

In Taunton, Mass Coastal operates the Dean Street Industrial Track, which runs approximately 1.5 miles from Weir Junction in Taunton north to Longmeadow Road near the Taunton/Raynham line. MCRR picks up/drops off cars for the Dean St. line at the Cotley siding track, the interchange point with CSX. In addition to the "main" track on the Dean Street line there are two double ended storage tracks adjacent to the Gallo Construction property, which occupies land between the Dean St. line and the CSX mainline to Attleboro. All three tracks are heavily used on a daily basis for switching and storage purposes to manage the large number of rock salt cars inbound and outbound from Gallo. Daily moves between Cotley Junction and the Dean Street line are required to deliver carloads and to retrieve empties.

4.1.3.2 Traffic Operations Analysis

This section presents information regarding existing traffic volumes, safety, and operational conditions along the highways or limited access freeway facilities in the study area. This section also provides existing safety and traffic operations information for the critical intersections at two existing park-and-ride lots. These park-and-ride lots, located in West Bridgewater and New Bedford, are important nodes as part of the No-Build (Enhanced Bus) Alternative. Based on field observations of current intersection operations and driveway configurations, these two locations appeared to have possible safety or capacity issues: The Mt. Pleasant Street park-and-ride facility in New Bedford and the Route 106/Route 24 park-and-ride access roadway intersection in West Bridgewater. These two unsignalized locations were analyzed further as they contain substantial parking capacity, exhibit some peak hour delay, and are located on higher volume collector and arterial roadways. The other park-and-ride locations were not studied for operations, as they appear to have less delay and or safety concerns.

Existing Traffic Volumes

Traffic volume data for the regional highway study area were collected in September and October 2008 and included ATRs. The location of all the traffic counters is shown in Figure 4.1-2.

Table 4.1-7 presents a summary of the recorded ATR volumes on a daily basis and during peak periods. Interstate 93 in Quincy carries approximately 175,000 vehicles per day (vpd) on a typical weekday, with approximately 7,800 northbound vehicles during the weekday morning peak hour and 7,300 vehicles during the weekday evening peak hour. Daily traffic volumes along Route 24 gradually increase from Fall River to Randolph more than doubling from approximately 49,000 vpd to 115,000 vpd.

To evaluate the traffic associated with No-Build (Enhanced Bus) Alternative, the TMCs were conducted during the weekday morning (7:00 to 9:00 AM) and weekday evening (4:00 to 6:00 PM) peak periods at the two park-and-ride lot study area intersections where such bus services would be provided to commuters driving to these lots These traffic volumes were reviewed, balanced, and rounded to the nearest five to develop the traffic volume networks used to evaluate existing traffic operations in the

vicinity of the park-and-ride lots associated with the future bus services. Peak hour traffic flow networks for the existing traffic to and from these Park-and-Ride bus stops during weekday morning and evening peak hours are shown in Figures 4.1-3 and 4.1-4 for the summer and fall, respectively.

Table 4.1-7 Existing Traffic Volumes—Regional Highways

Location (Figure 4.1-2 number)	ADT [1]	Direction	Weekday Morning Peak Hour	Weekday Evening Peak Hour

1 average daily traffic volume expressed in vehicles per day

Regional Growth

As the population in the South Coast Region and employment in the Boston area have grown, the demands on the roadway system linking Southeastern Massachusetts to the rest of the region have increased. Traffic volumes on the limited-access state routes linking the South Coast Region to the employment centers of Boston have been growing over the past decade, as shown in Table 4.1-8. Overall, traffic volumes on the roadways in the South Coast Region have grown at an annual rate of two to three percent over the past decade. However, traffic volumes have grown even more rapidly in some areas.

The largest increases in traffic volumes have been on Route 24 in Raynham and Taunton, where the traffic volumes have had annual increases of 4.1 and 5.0 percent respectively. Traffic volumes on Route 140 in Taunton have been increasing at an annual rate of 2.2 percent. Route 128 and I-93 (the Southeast Expressway) exhibit relatively stable traffic volumes. They are already some of the most congested highways in the state and traffic volumes on these roadways are at or near capacity for long portions of

the day, making further increases in average daily traffic volumes infeasible. The minor decrease in traffic on portions of I-93 may reflect changes in motorist route choices due to Central Artery/Tunnel project construction, and demand reductions from the Route 3 corridor due to the restoration of the Old Colony Commuter Rail service.

ADT Average Daily Traffic (vehicles per day)
Source: Massachusetts Highway Department

The increases in traffic volumes on the principal highways linking the South Coast region to downtown Boston have led to deteriorating LOS on these roadways, especially during peak periods. Delays on these roadways are now common and have become worse over the past decade. These delays are especially prevalent on Route 24 as it approaches Route 138/I-93 in Randolph. Increases to peak-hour volumes of up to 3,500 and 4,000 vehicles per hour on Route 24 and on I93/Route 138 in Braintree in Raynham, respectively, have led to deterioration of LOS down to F on these major roadways, which are intended to relieve the local roadways from regional traffic. Several mitigation measures have been implemented on I-93 to reduce congestion (high-occupancy vehicle lanes, improved MBTA Red Line service, and Old Colony Commuter Rail service). However, this highway continues to operate at poor levels of service, resulting in substantial congestion. There are no roadway alternatives to the use of Route 24 and I-93, and no mitigation measures are planned to reduce congestion.

The lack of adequate capacity of the roadway system and the resultant reduction in LOS is anticipated to become even more problematic with the increased demand for transportation resulting from the growth of the South Coast region, especially as commuters living near Boston are moving away to areas further from the metropolitan core. Southeastern Massachusetts has been one of the fastest growing areas in the Commonwealth. Between 1960 and 2000, this area experienced a growth rate of 31 percent. Between 1960 and 1990, this area had an annual growth of over 2,500 people per year from a base population of 343,353 to its 1990 population of 430,846. Growth slowed somewhat between 1990 and 2000, to an annual growth of approximately 1,950 people per year. These figures translate to a growth of 4.5 percent between 1990 and 2000, which is greater than the growth rate of the Commonwealth as a whole. Each 10,000 new residents coming into the area are expected to generate a need for 3,500 new residential units, and are predicted to generate 27,650 new vehicle trips per day, further degrading the level of service provided by the regional transportation system.

Furthermore, as described in greater detail in the next sections, the LOS of the roadway system connecting the South Coast region to Boston will deteriorate even further, resulting in a concurrent increase in congestion, accidents, travel time, and air pollution; not only on the highways themselves but potentially also on nearby local roadways that may absorb the traffic spillover from nearby congested highways.

Access from the South Coast region to Boston is primarily via Route 24 to Interstate 93. These principal, limited-access highways currently operate at or over capacity, with peak-hour volumes of up to 4,000 vehicles per hour and level-of-service F on Route 24 in Raynham, and 3,500 vehicles per hour and level-of-service F on I-93/Route 128 in Braintree. Notwithstanding the beneficial effects on reducing congestion of several transportation improvements such as high-occupancy vehicle lanes on I-93, improved MBTA Red Line service, and Old Colony Commuter Rail service, these measures have not been able to fully accommodate the growth in transportation demand between Boston and the South Coast region. Route 24 continues to operate at poor levels-of-service, resulting in substantial congestion and decreased safety. For travel between Boston and the South Coast region there are no other direct highway routes besides Route 24 and I-93. Measures to fundamentally reduce congestion on these highways have proven to be limited in their effectiveness. Roadway improvement measures are being proposed (as described in Chapter 2); however while these measures will improve intraregional traffic conditions they will not address the need for increased transportation capacity between the South Coast region and Boston.

Regional Transportation Conditions

The freeway/highway analysis portion of the study reviews highway capacity at critical locations along the I-93, Route 24, and Route 140 limited access freeways and Route 138. Highway capacity directly affects bus operations along each bus route to Boston. The highway corridors in Southeastern Massachusetts experience more congestion in the morning peak period as traffic increases in a northbound direction towards the urban core of Metropolitan Boston. Traffic volumes are substantially less as traffic travels southbound away from the Metropolitan Boston urban core with traffic peaking again to a lesser degree near the urban centers of New Bedford, Fall River, and Taunton.

Freeways/Highways

Thirteen freeway and highway locations were identified as important roadway segments that influence bus travel times to downtown Boston. These locations are segments located between major highway interchanges with substantial traffic merging and diverging at each highway interchange. The analyses include seven locations on Route 24, and two each on Route 140, Route 138, and I-93. The freeway/highway capacity analysis for these segments gives an understanding of the existing directional traffic operations on each segment for each weekday peak hour. However, it should be understood that highway operations are also impacted by merging/diverging traffic at interchanges.

Table 4.1-9 shows LOS for 13 freeway segments. All Route 24 locations, north of Route 44, operate at LOS D or E conditions in the peak direction in each peak hour. Route 24 south of Pond Street and Route 24 south of I-93 both have LOS E conditions during the weekday evening peak hour in a southbound direction. This coincides with the outbound evening commuter peak from Boston. I-93 south of Furnace Brook Parkway also has LOS E conditions during the weekday morning peak hour in a northbound direction. I-93 South of Route 3 does not exhibit worse than LOS D conditions because of lower volumes than on I-93 south of Furnace Brook Parkway. Although observed traffic conditions often times indicate heavy congestion (LOS E /F) on these segments, this is often associated with merging/diverging traffic between travel lanes and the HOV lane, construction activities, crashes, and other factors that are not considered in the freeway analysis methodology. The analysis results are only for the segments and do not reflect interchange circulation and event dynamics with resultant delay and queuing.

Table 4.1-10 shows the analysis results for Route 138 highway segments. The HCM analysis procedures for highways (which are not limited access or divided) differ from the freeway analysis procedures and are reported separately. The results indicate LOS D operations on these roadway segments in both peak hours.

Intersections

Intersection LOS was completed at park-and-ride locations observed with potential operational or safety issues. The two park-and-ride lots that were analyzed include West Center Street (Route 106) at Pleasant Street in West Bridgewater and Mt. Pleasant Street a park-and-ride lot in New Bedford.

In order to compare operations during off peak and peak seasonal traffic conditions, turning movement counts were completed during the summer and fall 2008. The West Bridgewater Route 106 park-and-ride lot is located directly south of Route 106 off of Pleasant Street. The lot is inaccessible by bus, so the Taunton bus parks outside the lot at the corner of Pleasant Street/internal connector roads to pick-up and drop-off passengers. The New Bedford Mt. Pleasant Street park-and-ride lot is located north of the Route 140 southbound ramps, on the east side of the street approximately 500 feet north of the ramp system.

The Route 106 park-and-ride lot is accessed via Pleasant Street or connector roads south of Route 106. Route 106 at this location is an arterial road with minimal gaps in traffic available at peak hour during the signal change at Route 106/Manley Street. Existing traffic operations indicate high delay for the minor street approach during the fall 2008 peak condition. During this period LOS for the Pleasant Street intersection minor approach is LOS F.

The Mount Pleasant Street park-and-ride lot is accessed directly from Mount Pleasant Street as a "T" type intersection. Mount Pleasant Street is a collector type road with average gaps at peak hour. Traffic operations indicate average to better than average delay for exiting traffic from the park-and-ride lot. During both summer and fall periods, traffic operations are acceptable at LOS C or better for all movements.

The HCM methodologies used for the analyses of unsignalized intersections are based on conservative analysis variables including periods of high critical gaps in traffic. However, actual traffic operations indicate that drivers on minor streets and driveways accept smaller gaps in traffic than the default values used in the analysis procedures and therefore experience less delay than reported by the HCM.

Also, the HCM methodologies do not fully take into account the beneficial grouping or platoon effects caused by the nearby signalized intersections. The results of HCM analysis procedures are the over-estimation of calculated delays at unsignalized intersections in the study area. A detailed review of the results should be completed when interpreting the capacity analysis results at unsignalized

intersections. A summary of the unsignalized capacity analyses during both the summer and fall 2008 is presented in Tables 4.1-11 and 4.1-12, respectively.

Table 4.1-11 Existing Conditions–Park-and-Ride Lots Intersection Level of Service Analysis (Summer 2008)

4 Indicates westbound left-through lane movement
5 Indicates northbound left-right lane movement
6 Indicates southbound left-through lane movement
7 Indicated westbound left-right lane movement

As indicated in Tables 4.1-11 and 4.1-12, the West Center Street (Route 106) at Pleasant Street intersection northbound approach is operating with substantial delay during the evening peak hour. This delay was evident in both the summer and fall 2008 analysis periods with delays being longer during the fall likely because of higher traffic volumes related to school and vacation schedules. The morning peak hour also operates at a deficient LOS F in the fall. Based on the traffic characteristics of this location, higher delay should be expected with the high volume on Route 106 and the multiple conflicts represented along Route 106 including traffic from the Route 24 southbound off ramp which deposits Route 106 westbound traffic immediately east of this intersection.

4.1.3.3 Safety Analysis

The three years of crash data (2004-2006) for the regional highways were obtained and reviewed. Summary tables for the safety analysis are provided in Appendix 4.1-B.

Freeway/Highway Safety

In order to identify crash trends, historical crash data were obtained from MassDOT Highway Division for the most recent three-year period available for the regional highways in the study area: I-93, Route 24, and Route 140. For each highway, vehicle crashes were compiled by specific community. Data analyzed for each crash include year of incident, crash type, severity, weather, and time of day.

A brief summary of the highway crash data by roadway is provided below for I-93, Route 24 and Route 140.

I- 93

- As might be expected of the section of I-93 with the highest traffic levels between Randolph through Boston, the Quincy section experienced 755 crashes (28 percent) during the three-year period.
- Fifty-seven percent of all the crashes were rear-end type collisions, typical of heavily congested corridors.
- Approximately 31 percent of the crashes involved fatalities or injuries, 59 percent involved property-damage only and 10 percent of the crashes were unknown.
- Seventy-two percent of the crashes occurred during dry conditions.

Route 24

- The Fall River section of Route 24 has experienced the most crashes (432 crashes or 15 percent) during the latest three year period. Approximately 36 percent of the crashes involved fatalities or injuries, 58 percent involved property-damage only, and 2 percent of the crashes were unknown.
- Sixty-nine percent of the crashes occurred during dry roadway conditions.
- Single vehicle and rear-end type collisions each represented 37 percent of total crashes.

Route 140

The limited access portion of Route 140 between Route 24 in Taunton and New Bedford experienced a total of 758 crashes in the most three year period for which data were available.

- Approximately 36 percent of the crashes involved fatalities or injuries, 59 percent involved property damage only.
- Seventy percent of the crashes occurred during dry pavement conditions.

Park-and-Ride Locations Intersection Safety

The following summarize the crash numbers and characteristics at the two proposed park-and-ride locations analyzed.

Route 106/Route 24 Park-and-Ride in West Bridgewater

The proposed park-and-ride facility would be located north of Route 106 (West Center Street) opposite Pleasant Street in the northwest quadrant of the Route 106/Route 24 interchange. Some of the issues prompting more detailed analysis of the Route 106 site include:

- The average daily traffic volume on Route 106 at this location is 23,500 vehicles per day based on the MassDOT Highway Division 2006 traffic volume database.
- The Pleasant Street/West Center Street (Route 106) intersection is unsignalized with STOP sign control on Pleasant Street.
- Traffic speeds on Route 106.
- The gaps in peak hour traffic are limited with high volumes in both directions.
- Observed minor street delay was substantial during peak hours.

Mount Pleasant Street Park-and-Ride Lot in New Bedford

The site of the proposed facility is in the northwest quadrant of the Route 140 and King's Highway interchange (Exit 4). Some of the issues prompting a more detailed analysis of the Mount Pleasant Street site include:

- The Mount Pleasant Street park-and-ride site driveway is located close to a horizontal curve that limits sight distance to the north.
- Based on recent utilization surveys completed in the summer and fall of 2008, this 201-space lot is heavily utilized at 80 percent of capacity.
- During peak hour this intersection experiences substantial turning and vehicle conflicts to enter and exit the parking lot.
- The average daily traffic volume on Mt. Pleasant Street at this location is 13,500 vehicles per day based on the MassDOT Highway Division 2004 traffic volume database.

In order to check the safety record of each location, crash records were obtained from MassDOT Highway Division. Each location has a crash rate that is substantially less than the MassDOT Highway Division District 5 average crash rate of 0.59 crashes per million entering vehicles for unsignalized intersections.

Traffic operations at these two park–and-ride facilities are discussed further in the intersection analysis section.

Summary of Existing Safety Conditions

The number of accidents on the primary travel routes within the South Coast region has generally been increasing over the past years. Projected future growth in traffic volume on the principal South Coast region roadways cannot be sustained by the current regional transportation system. Recurring traffic congestion is becoming a more significant problem for the region, as is the increasing frequency of traffic accidents, especially along congested roadway corridors. Traffic volume increases may thus contribute to increased risk of injury and property damage for the commuting public. Not only has the number of accidents increased, but also the number of injuries has increased on two area highways. The annual growth rate in injuries was 11.6 percent on Route 24 and 8.0 percent on Route 93. However, Route 140 experienced an annual decline rate in injuries, at -5.9 percent. Although increasing the capacity of the region's highways might improve safety temporarily, substantial highway capacity expansions are constrained by transportation policy and due to the constraints posed by available space within existing rights-of-way, the potential for physical expansion of the highway links is limited.

4.1.3.4 Grade Crossings

Conditions at existing grade crossings were identified, as the rail alternatives using these grade crossings would increase train frequency at these grade crossings and could thus affect traffic flows and roadway capacity on either side of each grade crossing. This section presents information regarding the existing grade crossings at each of the alternatives' alignment, including existing traffic volumes and the existing frequency of both commuter and freight train service at the existing grade crossings.

Southern Triangle Study Area (Common to All Build Alternatives)

There are 50 public and private existing grade crossings within the Southern Triangle. Existing train frequency at these crossings ranges from two to five roundtrip freight trains per week (four to ten trains in total). Specific data for each crossing are provided in Tables 4.1-13 and 4.1-14 for the New Bedford Main Line and the Fall River Secondary, respectively.

Whittenton Alternative—Attleboro Secondary Line

There are 10 public and private grade crossings within the Attleboro Secondary Line segment of the Whittenton Alternative alignment. Existing train frequency at these crossings ranges from two to five roundtrip freight trains per week (four to ten trains in total). Specific data for each crossing are provided in Table 4.1-15.

Stoughton/Whittenton Alternatives—Stoughton Line from Canton Junction to Weir Junction, including Whittenton Branch

There are 41 existing public and private grade crossings along these portions of the Stoughton and Whittenton alignments. Train frequency from Canton Junction station to Stoughton station, along the existing MBTA Stoughton Commuter Rail Line alignment, ranges from 16 roundtrip (32 total trains) passenger trains per day on weekdays to no passenger trains on weekends. There is also freight service several times a week between Canton Junction station and Central Street in Stoughton. There is no existing train frequency along the unused rail alignment from Stoughton station to Longmeadow Road in Taunton. Between Weir Junction and Longmeadow Road, train frequency is approximately two roundtrip freight trains (four total trips) per month. Train frequency near Ingell Street at Weir Junction varies weekly, approximately 10 roundtrip freight trains operated by CSX and three roundtrips operated by Mass Coastal weekly). The Whittenton Alternative has six public and private grade crossings along the currently inactive Whittenton branch. Specific data for each crossing are provided in Table 4.1-16.

4.1.3.5 Station Area Traffic Conditions

There are 12 potential new or relocated commuter rail stations proposed for the Stoughton and/or Whittenton Alternatives. These stations are located in the following communities:

- New Bedford—King's Highway and Whale's Tooth
- Freetown—Freetown
- Fall River—Fall River Depot and Battleship Cove
- Taunton—Taunton, Dana St. and Taunton Depot
- Stoughton—Stoughton (relocated)
- Easton—Easton Village and North Easton
- Raynham—Raynham Park

Traffic impact study areas were based on the proposed station locations. This section provides roadway and intersection inventories, traffic volume data, safety data, and traffic operations for each station study area.

Southern Triangle

New Bedford Stations Study Area (King's Highway Station and Whale's Tooth Station)

The traffic impact study areas within the City of New Bedford were selected for the two proposed commuter rail station locations. Figure 4.1-5 shows the location of the New Bedford stations and selected study area intersections.

New Bedford has two station locations proposed for all rail alternatives. The following paragraphs summarize the locations and features of the King's Highway stations and Whale's Tooth station.

The King's Highway station, located in northern New Bedford along King's Highway east of Route 140, would serve all of the rail alternatives. The station would serve walk-in, bike-in, and drive-in customers.

The Whale's Tooth station, located at the Whale's Tooth parking lot would serve all of the rail alternatives. Located on the New Bedford waterfront, the City of New Bedford has constructed a parking lot on the site in anticipation of the commuter rail project. The station would include intermodal connections, potentially including ferry services. The site would serve walk-in, bike-in, and drive-in customers with primary access from Herman Melville Boulevard.

Existing Traffic Volumes

Traffic volume data for the Whale's Tooth station and King's Highway station were collected in September 2008 and included ATR counts and manual TMCs. TMCs were collected in June and July 2009 for three intersections in the King's Highway station study area and one intersection in the Whale's Tooth station study area.

Table 4.1-17 presents a summary of the daily and peak hour roadway volumes. King's Highway carries the highest volume in the vicinity of the King's Highway station with approximately 19,500 vehicles per day (vpd) on a typical weekday, approximately 1,300 vehicles during the weekday morning peak hour and 1,500 vehicles during the weekday evening peak hour. Coggeshall Street carries the highest volume in the vicinity of the Whale's Tooth station with approximately 11,500 vpd on a typical weekday, approximately 750 vehicles during the weekday morning peak hour and 850 vehicles during the weekday evening peak hour.

The TMCs were collected during the weekday morning (7:00 to 9:00 AM) and weekday evening (4:00 to 6:00 PM) peak periods at each of the study area intersections. These volumes were reviewed, balanced and rounded to the nearest five to develop the traffic volume networks used to evaluate existing traffic operations. The morning network peak hour occurred from 7:45 to 8:45 AM and the evening network peak hour occurred from 4:00 to 5:00 PM. Peak hour traffic flow networks for an existing weekday morning and evening peak hour for Whale's Tooth and King's Highway stations are shown in Figures 4.1-6 through 4.1-9.

Table 4.1-17 Existing Traffic Volumes–New Bedford

Based on ATR counts conducted in September 2008.
1 average daily traffic (ADT) volume expressed in vehicles per day
2 peak period traffic volumes expressed in vehicles per hour
3 percent of daily traffic that occurs during the peak period
4 directional distribution of peak period traffic
Note: peak hours do not necessarily coincide with the peak hours of the individual intersection turning movement counts

Crash Analysis Summary—The New Bedford study area is made up of two separate subareas, the Whale's Tooth station and the King's Highway station. A total of 175 crashes occurred within the Whale's Tooth station study area, and 117 crashes occurred within the King's Highway station study area. There were seven intersections in the Whale's Tooth station study area and two intersections in the King's Highway station study area which exceeded the District 5 crash rates for signalized and unsignalized intersections.

The number of crashes and crash rates for the seven intersections that exceeded the District 5 crash rate in the Whale's Tooth station study area are:

- Four crashes occurred at the Acushnet Street at Hillman Street (0.65 vs. 0.59).
- Fourteen crashes occurred at the intersection of Purchase Street at Coggeshall Street (1.01 vs. 0.59).

- Sixteen crashes occurred at the intersection of Coggeshall Street at Acushnet Avenue/Route 18 Northbound (0.86 vs. 0.84).
- Fifty-one crashes occurred at the intersection of Coggeshall Street at Ashley Boulevard/Route 18 Southbound (2.92 vs. 0.84).
- Nine crashes occurred at the intersection of Logan Street at North Front Street (1.18 vs. 0.59).
- Fourteen crashes occurred at the intersection of Logan Street at Purchase Street (1.18 vs. 0.59).
- Six crashes occurred at the intersection of Wamsutta Street at Acushnet Avenue/Route 18 Northbound (3.30 vs. 0.59).
- Fifty percent of the crashes were angle type.
- Sixty-nine percent of the crashes occurred on dry pavement.

Two intersections (Church Street at Park Avenue (1.69 vs. 0.59) and King's Highway at Jones Street (0.64 vs. 0.59) exceed the District 5 crash rate in the King's Highway station study area.

- These intersections account for 38 percent of the incidents that occur in the King's Highway station study area.
- Sixty-one percent of the crashes at these two locations were angle type incidents. This may be a result of the high eastbound right turning volume.
- Forty-three percent of the crashes involved personal injuries and 48 percent involved property damage only.
- Sixty-eight percent of the crashes occurred during daylight hours on a dry road surface.

Traffic Operations Analysis—An analysis of the existing conditions near the Whale's Tooth and King's Highway stations was performed to assess the ability of intersections to process traffic. The results of the analyses for these intersections for 2008 Existing Conditions are presented in Table 4.1-18.

The Whale's Tooth station study area consists of seven signalized and eleven unsignalized intersections. Under existing conditions, two signalized intersections operate at deficient levels of service. The Union Street at Route 18 Southbound intersection operates at LOS F in the evening peak hour and LOS E in the morning peak hour due to heavy southbound through movements on Route 18 that are unable to adequately pass through the intersection in the allocated green time. The six approaches and moderate traffic volumes are the primary reasons that the Kempton Street at Purchase Street intersection operates at LOS F and E in the morning and evening peak hours, respectively. Three of the unsignalized intersections operate at a LOS E in the evening peak hour and one intersection operates at LOS E and F in the morning and evening peak hours, respectively. These unsignalized intersections experience long delays in the evening peak hour for left-turning movements from the minor street to the major street. The delays are primarily due to the high through traffic volumes on the major street.

Source: Synchro 7.0 Software; Build 763
1 average control delay for critical movements, rounded to the nearest whole second, for unsignalized intersections.
2 level of service
L = Left-turn; T = Through; R = Right-turn
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound
Shaded rows reflect the worst level of service intersections (LOS = F)

The King's Highway station study area consists of six signalized and five unsignalized intersections. All of the signalized intersections provide a good LOS in both the morning and evening peak hours. Two of the unsignalized intersections operate at LOS F in the morning and evening peak hours and two others operate at LOS F in the evening peak hour. These unsignalized intersections experience long delays for left-turning movements from the minor street to the major street. The delays are primarily due to the high through traffic volumes on the major street.

Freetown Station Study Area (Freetown Station)

The traffic impact study area within Freetown was selected based on the location of the proposed commuter rail station. Figure 4.1-10 shows the location of Freetown station and selected study area intersections.

The Freetown station, located on South Main Street south of the Route 24 and Route 79 interchange (Exit 9) would serve all of the rail alternatives. The station would serve drive-in customers and customers shuttled between the station and the nearby industrial parks, as well as pedestrians and bicyclists.

Existing Traffic Volumes—Traffic volume data for the Freetown station study area were collected in September 2008 and included ATRs and manual TMCs.

For the Freetown station study area, ATR data were collected on Route 79 between Route 24 northbound and southbound ramps (Exit 9) and on South Main Street, south of Route 24 Exit 9. Table 4.1-19 presents a summary of the daily and peak hour traffic volumes.

Table 4.1-19 Existing Traffic Volumes–Freetown

		Weekday Morning Peak Hour			Weekday Evening Peak Hour		
Location	**Daily Weekly Traffic[1]**	**Vol. (vph)[2]**	**"K" Factor[3]**	**Peak Directional Flow[4]**	**Vol. (vph)**	**"K" Factor**	**Peak Directional Flow**
S. Main St (Route 79), between Route 24 Ramps	10,100	825	8.1%	SB 70%	825	8.1%	SB 64%
S. Main St (Route 79), south of Route 24 Ramps	9,000	630	7.0%	SB 50%	705	7.8%	SB 50%

Based on ATR counts conducted in September 2008.
1 average daily traffic (ADT) volume expressed in vehicles per day
2 peak period traffic volumes expressed in vehicles per hour
3 percent of daily traffic that occurs during the peak period
4 directional distribution of peak period traffic
Note: peak hours do not necessarily coincide with the peak hours of the individual intersection turning movement counts

As presented in Table 4.1-19, Route 79 between the Route 24 Exit 9 ramps carries approximately 10,000 vehicles per day (vpd) on a typical weekday, with approximately 825 vehicles during the weekday morning peak hour and 825 vehicles during the weekday evening peak hour. South of the interchange, South Main Street carries approximately 9,000 vpd on a typical weekday, with approximately 650 vehicles during the weekday morning peak hour and 700 vehicles during the weekday evening peak hour.

The TMCs were collected during the weekday morning (7:00 to 9:00 AM) and weekday evening (4:00 to 6:00 PM) peak periods at each of the study area intersections. These volumes were reviewed, balanced and rounded to the nearest five to develop the traffic volume networks used to evaluate existing traffic operations. The morning network peak hour generally occurred from 7:00 to 8:00 AM and the evening network peak hour generally occurred from 4:15 to 5:15 PM. Peak hour traffic flow networks for an existing weekday morning and evening peak hour are shown in Figures 4.1-11 and 4.1-12, respectively.

Crash Analysis Summary—Crash rates at the intersections analyzed were less than the District 5, and Massachusetts statewide averages. Crashes occurred over the most recent three year period from 2004 to 2006. A brief summary of the crash data shows that:

- Most of the crashes that occurred in the study area are angle type (60 percent) collisions.
- The majority of the crashes occurred during the daylight hours (70 percent) on dry roadways (80 percent).

Traffic Operations Analysis—An analysis of the existing conditions in the vicinity of the Freetown station site was performed to assess the ability of intersections to process traffic. The results of the analyses for these intersections for 2008 Existing Conditions are presented in Table 4.1-20.

Table 4.1-20 Freetown Intersection Capacity Analysis—Existing Conditions

	Weekday Morning Peak Hour			Weekday Evening Peak Hour		
Unsignalized Intersections	Critical Movement	Delay[1]	LOS[2]	Critical Movement	Delay[1]	LOS[2]

Source: Synchro 7.0 Software; Build 763
1 average control delay by for the critical movement, rounded to the nearest whole second, for unsignalized intersections.
2 level of service
L= Left-turn; T = Through; R = Right-turn
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Under existing conditions, the Freetown station study area consists of six unsignalized intersections. Two of the unsignalized intersections currently operate at LOS E in the morning peak hour. Both those intersections as well as a third intersection operate at LOS E in the evening peak hour. These unsignalized intersections experience long delays in the evening peak hour for left-turning movements from the minor street to the major street. The delays are primarily due to the high through traffic volumes on South Main Street.

Fall River Stations Study Area (Battleship Cove Station and Fall River Depot Station)

The traffic impact study areas within the City of Fall River were selected based on the proposed commuter rail station locations. Figure 4.1-13 shows the location of the Fall River stations and selected study area intersections.

Fall River has two station locations proposed for the rail alternatives. The following paragraphs summarize the locations and features of the Battleship Cove and Fall River Depot stations.

Located within a block of Battleship Cove, the proposed Battleship Cove station is not anticipated to serve a substantial amount of regular commuter rail ridership. The station is intended, rather, to provide tourist access to the attractions at Battleship Cove with limited parking available. Traffic analysis for

existing conditions was completed for this station study area, however future conditions analysis may only focus on pedestrian circulation and improving existing infrastructure deficiencies rather than full traffic impact analysis.

The Fall River Depot station, located 1 mile north of downtown Fall River at Route 79 and Davol Street, would serve all the rail alternatives. The site is envisioned to be a multi-modal transportation center with new mixed-use development and parking facilities. The site would serve walk-in, bike-in, and drive-in customers. Access will likely be provided from either Pierce Street or North Main Street in proximity to the Route 79 corridor.

Existing Traffic Volumes—Traffic volume data for the Battleship Cove station and Fall River Depot station were collected in September and October 2008 and included ATR counts and manual TMCs.

For the Battleship Cove station study area, ATR data were collected at the North Davol Street northbound U-turn, which merges with Davol Street Southbound near Cedar Street. Table 4.1-21 presents a summary of the daily and peak hour volumes.

As presented in Table 4.1-21, the North Davol Street U-turn (to Davol Street southbound) carries approximately 500 vehicles per day (vpd) on a typical weekday, with approximately 45 vehicles during the weekday morning peak hour and 40 vehicles during the weekday evening peak hour. The Davol Street U-turn to South Davol Street northbound carries twice as much on a daily basis. North Davol Street, south of President Avenue in the vicinity of the Fall River Depot station carries approximately 8,000 vpd northbound. Davol Street in the same area carries 10,000 vpd southbound on a typical weekday. In the morning peak hour approximately 500 vehicles travel northbound and 850 vehicles travel southbound, while in the evening peak hour 500 vehicles travel northbound and 650 vehicles travel southbound.

Table 4.1-21 Existing Traffic Volumes–Fall River

		Weekday Morning Peak Hour			Weekday Evening Peak Hour

Davol St., south of President Ave.	10,800	830	7.7%	SB 100%	635	5.9%	SB 100%

Based on ATR counts conducted in September and October 2008.
1 average daily traffic (ADT) volume expressed in vehicles per day
2 peak period traffic volumes expressed in vehicles per hour
3 percent of daily traffic that occurs during the peak period
4 directional distribution of peak period traffic
Note: peak hours do not necessarily coincide with the peak hours of the individual intersection turning movement counts

The TMCs were collected during the weekday morning (7:00 to 9:00 AM) and weekday evening (4:00 to 6:00 PM) peak periods at each of the study area intersections. These volumes were reviewed, balanced and rounded to the nearest five to develop the traffic volume networks used to evaluate existing traffic operations. The morning network peak hour generally occurred from 7:15 to 8:15 AM and the evening network peak hour generally occurred from 4:15 to 5:15 PM. Peak hour traffic flow networks for an existing weekday morning and evening peak hour are shown in Figures 4.1-14 and 4.1-15.

Crash Analysis Summary—Crash rates at the following Fall River intersections exceed the statewide average:

- North Davol Street at President Avenue (2.42 vs. 0.84 – 60 crashes)
- North Main Street at President Avenue (1.14 vs. 0.84 – 29 crashes)
- Water Street at Anawan Street (0.63 vs. 0.59 – 4 crashes)

A total of 117 crashes occurred over the three-year period from 2004 to 2006, with the majority (76 percent) occurring at the intersection of North Davol Street at President Avenue. A brief summary of the crash data shows that:

- Most of the crashes that occurred in the study are angle type (44 percent) and rear-end type (31 percent) collisions.
- There were no fatalities between the years 2004 and 2006.

Traffic Operations Analysis—An analysis of the existing conditions in the vicinity of the Fall River Depot station and Battleship Cove station was performed to assess the ability of intersections to process traffic. The results of the analyses for these intersections for 2008 Existing Conditions are presented in Table 4.1-22.

The Battleship Cove station study area consists of four unsignalized intersections. The Central Street at Davol Street intersection operates at LOS E in the morning and LOS F in the evening peak hours. This intersection experiences long delays due to heavy westbound movements from the minor street (Central Street). Anawan Street at Davol Street is an all-way STOP-controlled intersection that currently operates at LOS F in the morning and evening peak hours. This intersection experiences long delays due to heavy southbound movement from Anawan Street onto Davol Street.

Under existing conditions, the Fall River Depot station study area consists of three signalized and four unsignalized intersections. All of the signalized and unsignalized intersections provide a good LOS (LOS C or better) in both the morning and evening peak hours.

Taunton Stations Study Area (Taunton Station, Dana St. Station and Taunton Depot Station)

The traffic impact study areas within the City of Taunton were selected based on the proposed commuter rail station locations. Figure 4.1-16 shows the location of the various Taunton stations and selected study area intersections.

There are three proposed stations located in Taunton, the Taunton, Taunton Depot, and Dana Street Stations. Although only the Taunton Depot Station is located in the Southern Triangle, all three stations are addressed in this section.

The Taunton Depot station, located at the rear of Target Plaza, would serve the Stoughton and Whittenton Alternatives. This station site is approximately 14 acres and is located off of Route 140. The station would serve customers that drive to the station, as well as potential future walk-in or bike-in customers if redevelopment were to occur in the area.

The Taunton station, located along Arlington Street near Dean Street (Route 44), would serve the Stoughton Alternative. The location is within walking distance of downtown Taunton. The station would be a multimodal transportation center serving walk-in, bike-in, and drive-in customers.

Since the DEIS/DEIR, the Downtown Taunton Station site has been developed and is no longer available for the South Coast Rail project. The Dana Street Station would instead become the station that serves the Whittenton Alternative. The Dana Street Station is approximately 0.5 mile north of the previously-proposed Downtown Taunton Station and would be served by many of the same roadways that provided access to the Downtown Taunton Station.

Existing Traffic Volumes—Traffic volume data for the Taunton Depot and Taunton stations were collected in September and October 2008 and included ATR counts and manual TMCs. Table 4.1-23 presents a summary of the daily and peak hour traffic volumes. The highest daily two-way volume for an undivided roadway was almost 29,000 vehicles on Route 44 (Dean Street) west of Route 104. The peak hour volumes at that location were also the highest with 1,850 and 1,975 vehicles, respectively, in the morning and evening. The highest daily volume in one direction was about 22,700 vehicles on Route 140 westbound between the Route 24 ramps. The eastbound direction in that location carried about 12,400 vehicles for a daily two-way volume of 35,100.

Based on ATR counts conducted in September and October 2008.
1 average daily traffic (ADT) volume expressed in vehicles per day
2 peak period traffic volumes expressed in vehicles per hour
3 percent of daily traffic that occurs during the peak period
4 directional distribution of peak period traffic
Note: peak hours do not necessarily coincide with the peak hours of the individual intersection turning movement counts

Crash Analysis Summary—A total of 345 crashes occurred in the Taunton study area over the three-year period from 2004 to 2006. Crash rates at the following eight intersections were all higher than the District 5 and Massachusetts statewide averages.

- Hart Street at County Street/Route 140
- Stevens Street /County St at Route 140 NB Ramps/Galleria Mall Ramp
- Kilmer Street at Lowell St at Oak Street
- Post Office Square at Taunton Green Street at Court Street
- Longmeadow Road/Hon Gordon Owen Riverway at Dean Street/Route 44
- School Street at Arlington Street /Purchase Street
- Spring Street at Summer Street (Route 140)
- Winter Street at School Street
- Purchase Street at Washington Street (This intersection had an extremely high calculated crash rate of 3.77 [vs. a District 5 average of 0.59]. There was a large occurrence of angle type collisions [92 percent] that may be due to the large northbound left turn movement.)

A brief summary of the crash data shows that:

- 62 percent of all the crashes involved property-damage only. Twenty-nine percent of the crashes involved a non-fatal injury
- 57 percent of the crashes were angle-type collisions

Traffic Operations Analysis—An analysis of the existing conditions in the vicinity of the Taunton Depot and Taunton stations was performed to assess the ability of intersections to process traffic. The results of the analyses for these intersections for 2008 Existing Conditions are presented in Table 4.1-24.

Under existing conditions, the Taunton Depot station study area consists of seven signalized intersections. Only one location operates at a deficient LOS. Route 140 at the Route 24 southbound ramps operates at LOS F in the evening peak hour due to long delays for the left-turning eastbound traffic from the Route 24 ramp. It appears that the delay is primarily due to lack of adequate capacity to accommodate the high traffic volume on the Route 140 southbound approach.

Peak hour traffic flow networks for an existing weekday morning and evening peak hour are shown in Figures 4.1-17 and 4.1-18.

The Taunton station study area consists of seven signalized and three unsignalized intersections. All of the signalized intersections provide a good LOS in both the morning and evening peak hours except for Route 44 at Longmeadow Road, which operates at a LOS F and E during the morning and evening peak hours, respectively. One unsignalized intersection operates at LOS F in both the morning and evening peak hours and another operates at LOS F in the evening peak hour. These locations experience long

delays for the minor street movements that are unable to find suitable gaps in the main street traffic. The delays are primarily due to the high through traffic volumes on the major street.

Stoughton Alternatives

Relocated Stoughton Station Study Area

Existing traffic conditions and impacts that could result from the South Coast Rail project in the vicinity of the existing Stoughton Station were not evaluated as part of the DEIS/DEIR because no changes to parking at this station were proposed at the time. As discussed in Chapter 3, subsequent to the DEIS/DEIR, MassDOT has proposed relocating Stoughton Station. The station would be shifted from its present location between Porter and Wyman streets to a new location south of the Wyman Street at-grade crossing. As a result, an inventory of existing transportation conditions and potential impacts was prepared to address the change in the location of the station platform, consolidation of parking and addition of new station driveways; and the increase in the number of parking spaces.

A field inventory of traffic conditions on study area roadways was conducted in April 2012. Nine intersections were included in the study area (Figure 4.1-19). Descriptions of intersection and roadway geometry, along with field inventory notes are provided in Appendix 4.1-K.

Existing Traffic Volumes—Traffic volume data for the intersections shown in Figure 4.1-19 were collected in April 2012. TMCs were conducted at the entrance and exit points to the existing MBTA parking lot driveways. Figure 4.1-19 shows the study area intersections as well as the entrance and exit locations of the existing MBTA parking lots.

Forty-eight hour ATR data were collected along Washington Street and Brock Street. Table 4.1-25 presents a summary of the recorded ATR volumes on a daily basis and during peak hours.

Traffic volumes include about 3,300 daily vehicles along Brock Street and 13,550 daily vehicles along Washington Street. Peak hour traffic represents 6 to 10 percent of the overall daily volume on the roadway network, meaning that there is a constant flow of traffic traveling along these roadways during the majority of the day.

Speed data were also collected along Washington Street and Brock Street in the locations described above. The average speeds along Washington Street and Brock Street were 33 mph and 26 mph, respectively.

Table 4.1-25 Stoughton Station Existing Traffic Volumes

Location	Daily Weekday[2]	Weekday Morning Peak Hour			Weekday Evening Peak Hour

4 percent of weekday daily traffic that occurs during the peak hour
5 directional distribution of traffic

Crash Analysis Summary—Appendix 4.1-K provides the vehicle crash data for the study area intersections between 2007 and 2009. The crash data show that angle crashes were the leading type of crashes, followed by rear end crashes. The majority of crashes occurred on dry pavement, during off-peak times on a weekday. Approximately 74 percent of crashes resulted in property damage only.

During the 3-year period, the intersection of Pleasant Street at Park Street/ Washington Street had the highest number of crashes (35), which included a crash that involved a bicyclist. Wyman Street at Washington Street and Brock Street/ Kinsley Street at Washington Street were the intersections with the next highest number of accidents, with 23 accidents and 22 accidents, respectively.

Pleasant Street at Park Street/Washington Street exceeds both the state and district crash rate. For unsignalized intersections, Brock Street at Morton Street and Wyman Street at Brock Street are the only intersections with crash rates below the state and district crash rates. Crash rate calculations are provided in Appendix 4.1-K.

Traffic Operations Analysis—The existing traffic operations conditions were determined using the existing traffic volume networks. The morning and evening peak hour volume networks are depicted in Figures 4.1-20 and 4.1-21. The results of the signalized and unsignalized intersection capacity analyses for each of the study area intersections are summarized in Table 4.1-26 and 4.1-27, respectively. Complete traffic operations data for each location are provided in Appendix 4.1-K.

Table 4.1-26 Stoughton Station Existing Conditions Signalized Intersection Capacity Analysis

		Existing Conditions		
Location	**Period**	**v/c[1]**	**Delay[2]**	**LOS[3]**
Porter Street at Washington Street	Weekday Morning	0.69	21	C
	Weekday Evening	0.90	49	D
Pleasant Street at Park Street/ Washington Street	Weekday Morning	0.92	36	D
	Weekday Evening	0.79	24	C

Source: Synchro 7 (Build 773, Rev 8) software
Notes:
1 volume-to-capacity ratio
2 average delay in seconds per vehicle
3 level of service

As shown in Table 4.1-26, both signalized intersections operate at acceptable levels of service under existing conditions. As indicated in Table 4.1-27, stop-controlled approaches to three unsignalized study area intersections operate at unacceptable LOS E or LOS F conditions.

Two intersections in the Stoughton Station study area experience excess queues during peak hours:

- The queue for eastbound Porter Street at the intersection with Washington Street exceeds the available storage length by approximately 60 feet during the evening peak hour. The northbound left-turn lane queue on Washington Street exceeds the available storage length by approximately 350 feet during the morning and evening peak hour. The queue on Southbound Washington Street exceeds the available storage length by 450 feet.

- For the intersection of Pleasant Street at Park Street/Washington Street, the northbound, southbound left turn, and through lanes on Park Street all experience queues that are longer than the available storage length during both the morning and evening peak hour.

Average queues for all lanes at the study area intersections are accommodated with two exceptions on Washington Street: the northbound left-turn lanes and southbound through lanes between the intersections with Freeman Street and Porter Street. The average queue is 120 feet in excess of available storage along the northbound direction and 60 feet in the southbound direction. See Appendix 4.1-K for details of the queue analysis.

Note: Shaded cells denote LOS E/F conditions.
1 demand in vehicles per hour for unsignalized intersections
2 volume-to-capacity ratio for the critical movement, values over 1.0 indicate demand in excess of capacity.
3 Control delay per vehicle, expressed in seconds, includes initial deceleration delay, queue move-up time, stopped delay, and final acceleration delay.
4 level of service of the critical movement
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound; LT = left-turn; TH = through; RT = right-turn, Neg = negligible

Pedestrians and Bicycles—Stoughton Station is currently accessible via Porter Street, Wyman Street, Morton Street, Brock Street and Washington Street. Sidewalks are provided on the east side of Morton Street, north side of Brock Street and along both sides of Porter Street, Wyman Street and Washington Street.

Parking—Parking for Stoughton Station commuters is currently provided in a number of parking lots accessible from Porter Street, Wyman Street and Washington Street.

Public Transportation—The Providence/Stoughton Line is the only public transportation provided by the MBTA in this area. The existing Stoughton Station ridership is approximately 1,050 inbound boardings per day. The Brockton Area Transit Authority (BAT) provides a bus service between the Brockton Area Transit Center and Cobbs Corner via Washington Street with stops at the Westgate Mall, south of the study area, along Washington Street, and a terminal stop at Cobbs Corner, north of the study area. BAT provides services Monday through Saturday between 6:00 AM and 6:00 PM.

Easton Station Study Area

The traffic impact study areas within the Town of Easton were selected based on the locations of the proposed commuter rail stations. Figure 4.1-22 shows the location of the Easton stations and selected study area intersections.

Easton has two station locations proposed for the Stoughton Alternative. The following paragraphs summarize the locations and features of the Easton Village and North Easton stations.

The Easton Village station is proposed to be located next to the Old Colony Railroad Station which is part of the discontiguous H.H. Richardson National Historic Landmark. The site is currently limited to the railroad right-of-way and is within walking distance of downtown Easton. The site would be a village-style station serving walk-in and bike-in customers. No commuter parking would be provided, however approximately 12 kiss and ride spaces would be designated in an existing private lot. Traffic analysis for existing conditions was completed for this station study area, however, future conditions analysis may only focus on pedestrian circulation and improving existing infrastructure deficiencies rather than full traffic impact analysis.

The North Easton station is proposed on the Stoughton town line at the rear of the Roche Brothers plaza and accessible from an existing traffic signal on Route 138. The station would have a surface parking lot and would primarily serve drive-in customers, although the station may also attract some walk-in customers from the existing plaza development and from limited nearby residences.

Existing Traffic Volumes—Traffic volume data for the Easton Village and North Easton stations within the Easton study area were collected in September 2008 and included ATRs and manual TMCs. Table 4.1-28 presents a summary of the daily and peak hour volumes. Route 138 north of Elm Street carries the highest traffic volumes near the North Easton station. It carries approximately 19,500 vehicles per day (vpd) on a typical weekday, with approximately 1,700 vehicles during the morning peak hour and 1,650 vehicles during the evening peak hour.

The TMCs were collected during the weekday morning (7:00 to 9:00 AM) and weekday evening (4:00 to 6:00 PM) peak periods. The volumes were reviewed, balanced and rounded to the nearest five to develop the traffic volume networks used to evaluate existing traffic operations. The network morning peak hour occurred from 7:15 to 8:15 AM and the network evening peak hour occurred from 4:45 to

5:45 PM. Peak hour traffic flow networks for an existing weekday morning and evening peak hour are shown in Figures 4.1-23 and 4.1-24, respectively.

Table 4.1-28 Existing Traffic Volume Summary–Easton

		Weekday Morning Peak Hour			Weekday Evening Peak Hour		
Location	Daily Weekly Traffic [1]	Vol. (vph)[2]	"K" Factor[3]	Peak Directional Flow[4]	Vol. (vph)	"K" Factor	Peak Directional Flow
Route 138, south of Main St.	17,000	1,395	8.2%	NB 61%	1,415	8.3%	SB 53%
Route 138, north of Elm St.	19,400	1,690	8.7%	NB 75%	1,660	8.6%	SB 60%
Route 138, north of Roche Bros.	15,200	1,455	9.6%	NB 72%	1,355	8.9%	NB 62%
Main St, east of Center St.	13,600	1,160	8.5%	EB 76%	1,140	8.3%	WB 60%

Based on ATR counts conducted in September and October 2008.
1 average daily traffic (ADT) volume expressed in vehicles per day
2 peak period traffic volumes expressed in vehicles per hour
3 percent of daily traffic that occurs during the peak period
4 directional distribution of peak period traffic
Note: peak hours do not necessarily coincide with the peak hours of the individual intersection turning movement counts

It should be noted that the Central Street Bridge was closed during the initial data collection period. Subsequent traffic counts were conducted in 2009 and traffic volumes did not change within the Route 138 and Center Street corridors.

Crash Analysis Summary—A total of 79 crashes occurred in the Easton study area over three-year period from 2004 to 2006. Only the crash rate at the intersection Elm Street at North Main Street exceeded the MassDOT District 5 average crash rate. The following summarizes the crash data:

- The majority of the crashes in the area appear to be at the intersections of Route 138/Washington Street at Elm Street (17 crashes), and Route 138/Washington Street at Main Street (24 crashes);
- Fifty-nine percent of all the crashes in this area were angle-type collisions; and
- Sixty-five percent of the crashes involved property damage only. Twenty-seven percent of the crashes involved injury to one or more persons. None of the crashes were fatal.

Traffic Operations Analysis—An analysis of the existing conditions in the vicinity of East Village station and North Easton station was performed to assess the ability of intersections to process traffic. The results of the analyses for these intersections for 2008 Existing Conditions are presented in Table 4.1-29.

Under existing conditions, the North Easton station study area consists of one signalized and two unsignalized intersections. The signalized intersection provides a good LOS in both the morning and evening peak hours. The two unsignalized intersections on Route 138 operate at a LOS F in the morning and evening peak hours. These intersections experience long delays for the minor street traffic that is unable to find suitable gaps in the main stream traffic. The delays are primarily due to high through traffic volumes on Route 138.

Table 4.1-29 Easton Intersection Capacity Analysis—Existing Conditions

4 average control delay for the critical movement, rounded to the nearest whole second, for unsignalized intersections.
L = Left-turn; T = Through; R = Right-turn
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound
Shaded rows reflect the worst level of service intersections (LOS = F).

The Easton Village station study area consists of two signalized and four unsignalized intersections. One of the signalized intersections (Route 138 at Main Street) operates at a LOS F in the morning peak hour due to heavy eastbound left-turning movements from Main Street that cannot be processed through the intersection in the allocated green time. The unsignalized intersection of Main Street at Center Street and Lincoln Street operates at LOS F in both the morning and evening peak hours. Roosevelt Circle at Route 138 operates at LOS E in the morning peak hour. These intersections experience long delays for the minor street traffic that is unable to find suitable gaps in the main road traffic. The delays are primarily due to the high traffic volume on Route 138.

Raynham

The traffic impact study areas within the Town of Raynham were selected based on the locations of the proposed commuter rail station. Figure 4.1-25 shows the location of the Raynham Park station and selected study area intersections.

The Raynham Park station, located at the former Raynham-Taunton Greyhound Park in Raynham, would serve the Stoughton Alternative. The site is now occupied by a simulcast center, and has a large surface parking lot along Route 138 near the Raynham/Easton town line. The site would serve mostly drive-in customers with additional walk-in customers being drawn from planned redevelopment on the site.

Existing Traffic Volumes—Traffic volume data for the Raynham Park station were collected in September 2008 and included ATR counts and manual TMCs. ATR data were collected at Route 138

north of the Dog Track. Table 4.1-30 presents a summary of daily and peak hour volumes. Route 138 carries 17,000 vehicles daily and 1,460 and 1,560 vehicles, respectively in the morning and evening peak hours.

Table 4.1-30 Existing Traffic Volume Summary–Raynham

		Weekday Morning Peak Hour			Weekday Evening Peak Hour		
Location	Weekly Daily Traffic[1]	Vol. (vph)[2]	"K" Factor[3]	Peak Directional Flow[4]	Vol. (vph)	"K" Factor	Peak Directional Flow
Route 138, north of Dog Track	17,060	1,460	8.6%	NB 76%	1,560	9.2%	SB 67%

Based on ATR counts conducted in September 2008.
1 average daily traffic (ADT) volume expressed in vehicles per day
2 peak period traffic volumes expressed in vehicles per hour
3 percent of daily traffic that occurs during the peak period
4 directional distribution of peak period traffic
Note: peak hours do not necessarily coincide with the peak hours of the individual intersection turning movement counts

Crash Analysis Summary—A total of 34 crashes occurred during the three-year period from 2004 to 2006 in the Raynham study area. Crash rates at all intersections were less than the District 5 and Massachusetts statewide averages. The following summarize some of the crash data:

- Forty-six percent of all crashes in this area are angle-type collisions.
- Forty-nine percent of the crashes in this area contained damage to property only.
- Thirty-two percent of the crashes involved a non-fatal injury. No fatal crashes occurred in this area.

Traffic Operations Analysis—An analysis of the existing traffic operating conditions in the vicinity of the Raynham Park station was performed to assess the ability of intersections to process traffic. The results of the analyses for these intersections for 2008 Existing Conditions are presented in Table 4.1-31.

The Raynham Park station study area consists of three signalized and eight unsignalized intersections. Under existing conditions, all the signalized intersections provide a good LOS in both the morning and evening peak hours.

Five of the unsignalized intersections operate at LOS E or F in both the morning and evening peak hours. These intersections experience long delays for the minor street traffic that is unable to find suitable gaps in the high volume of Route 138 through traffic. Peak hour traffic flow networks for an existing weekday morning and evening peak hours are shown in Figures 4.1-26 and 4.1-27, respectively.

4.1.4 Analysis of Impacts by Alternative

4.1.4.1 No-Build (Enhanced Bus) Alternative

The No-Build Alternative includes enhanced bus service. The impact analysis of the No-Build Alternative is focused on the roadways serving each station in the study area and analyzes its impact on traffic operations. No analyses of pedestrian and bicycle conditions, parking, or public bus transit service were conducted for the No-Build Alternative because they are not expected to change near proposed station locations. The purpose of the No-Build analysis is to provide a base against which the results of the analysis of the Build Alternatives can be compared to determine the impacts of each Build Alternative.

The No-Build (Enhanced Bus) Alternative consists of potential transportation improvements for the Boston commute to and from South Coast communities that could be implemented at minimal cost and limited impact to the environment. Currently, South Coast commuters to Boston must drive (alone, or in a carpool), commute to the nearest bus station, commute to a park-and-ride facility, or commute to a MBTA commuter rail station. The closest existing MBTA commuter rail stations with linkage to Boston are located outside the South Coast region in Attleboro, South Attleboro, Mansfield, and Lakeville. Refer to Chapter 3 for a detailed description of the No-Build Alternative.

Background Development/Infrastructure Improvements

While the CTPS travel demand model accounts for the majority of future development areas within its demographic forecasts, a number of large development projects were not specifically included in the

model's future land use assumptions. Identification of these projects was coordinated with the Massachusetts Environmental Policy Act office, MassDOT Highway Division, SRPEDD, and OCPC. The No-Build Alternative transportation analysis includes travel demands from these specific planned developments in the study area, roadway improvements planned or programmed to be completed by or before 2030, and bus service improvements. These development projects and transportation improvements, including bus enhancements, are described in detail in Appendix 4.1-L. The existing traffic volume networks were projected into future conditions using annual traffic growth factors combined with project-specific traffic volumes to the traffic volumes to create the 2030 No-Build condition traffic volume networks, which are depicted in Figures 4.1-28 through 4.1-43.

Traffic Operations Analysis

The following section describes how the No-Build (Enhanced Bus) Alternative was analyzed for traffic operations. Traffic operations on Route 24, Route 140, I-93, Route 138, and at the driveways to new and expanded park-and-ride facilities were analyzed to assess the impact of the enhanced bus service under 2030 No-Build conditions. Intersections around each proposed rail station location were analyzed to establish a base condition for projecting traffic impacts from the rail alternatives.

Traffic operations were analyzed for the No-Build Alternative using the methodology previously described. The results of these analyses are presented in tables that include existing LOS and highlight locations that would operate at unacceptable levels of service during at least one peak hour. Intersections that would degrade to unacceptable levels of service under 2030 No-Build conditions are denoted in **bold**. LOS analyses for all highways and intersections are provided in Appendix 4.1-I

CTPS provided ridership projections by transportation mode for the South Coast Rail project in the 2030 horizon year as well as projections for future traffic growth along the major corridors between Boston and the South Coast. The No-Build Enhanced Bus Alternative ridership projections and projected freeway volumes were used to analyze expected future traffic conditions. Traffic volume estimates from the specific No-Build development projects were added to the CTPS traffic volume projections to create the 2030 No-Build condition traffic volume networks, which are shown in Figures 4.1-28 through 4.1-43.

The freeway analysis includes 11 locations on Route 24, Route 140, and I-93. The highway analysis was conducted for two locations on Route 138 in Taunton and Easton. Intersection analyses were conducted for the park-and-ride facility driveways on West Center Street in West Bridgewater and on Mt. Pleasant Street and Acushnet Street in New Bedford. The analysis results for intersections near each proposed rail stations are presented by municipality below.

Freeways/Highways

LOS was reviewed on two freeway segments on I-93, nine segments on Route 24, and two segments on Route 140. Table 4.1-32 provides the results of the freeway operations analysis. The results of the analysis indicate that freeway levels of service are expected to decline in the peak direction (northbound in the morning peak hour and southbound in the evening) on a number of segments. Typically, there is a one-letter grade reduction at each location. On eleven segments, the decline results in a deficient LOS, especially in the northbound direction during the morning peak hour. The most dramatic changes would occur near the Fall River-Freetown line in the vicinity of the new Exit 8A interchange because of proposed new development in that area.

1 Level of service
2 Vehicles per hour
3 Passenger cars/per mile/per lane

Table 4.1-33 depicts the highway operations for 2030 under the No-Build Alternative. Based on CTPS and historical growth projections, traffic volumes were projected to 2030 No-Build conditions. The results of the 2030 highway capacity analysis indicate that the two segments of the highway analyzed are expected to continue to operate at LOS D during each peak hour.

Table 4.1-33 2030 No-Build Highway Capacity Analyses Summary–Route 138

2 Vehicles per hour
3 Volume to capacity ratio

Intersections (Enhanced Bus Park-and-Ride Locations)

In order to evaluate the proposed access for the bus park-and-ride locations under future conditions, intersection capacity analyses were performed at driveway locations using 2030 projected traffic volumes. For the two existing park-and-ride locations, traffic volumes for the 2030 design year were projected based on the estimated annual growth rate and by adding additional vehicle trips associated with the increased ridership projections provided by CTPS. Volumes were projected using the existing fall 2008 volumes as a base, which represent a more conservative analysis than the summer 2008 volumes.

Results for the capacity analyses of the two signalized intersections providing access to the new expanded Galleria Mall park-and-ride lot in Taunton are summarized in Table 4.1-34, which also depicts the 2030 No-Build analysis at the park-and-ride lot proposed in West Bridgewater on Route 106 and at the two lots proposed in New Bedford on Mt. Pleasant Street and Acushnet Avenue (Whale's Tooth). All three locations are unsignalized.

Galleria Mall Park-and-Ride, Taunton—In order to assess the impacts of additional ridership predicted at the new expanded Galleria Mall park-and-ride in Taunton, capacity at the nearby signalized intersections that provide access to the Mall were reviewed for the 2030 No-Build Alternative. The two intersections reviewed include Stevens Street at the Route 140 Northbound Ramps and County Street at the Galleria Mall Drive/Route 140 Southbound on-ramp. The analyses assumed no geometric or traffic control changes are proposed under future 2030 conditions. The added traffic volume from the expected increase in ridership was distributed to the two intersections based on existing travel patterns. The results of the analyses indicate that the weekday morning and weekday evening peak hour LOS at the Stevens Street at Route 140 Ramps is expected to remain at LOS B under future volume conditions. Weekday morning and weekday evening peak hour LOS is expected to remain at LOS A at the intersection of County Street at Galleria Mall Drive/Route 140 southbound ramp. The results conclude that the added traffic from the expanded park-and-ride will not impact the capacity of the intersections that provide access to the site.

Route 106 Park-and-Ride, West Bridgewater—The proposed park-and-ride facility in West Bridgewater would use an existing driveway at the intersection of Pleasant Street and West Center Street (Route 106). No geometric or traffic control changes are proposed under future 2030 conditions. Weekday morning and evening peak hour levels of service on the West Center Street (Route 106) approach are expected to remain at LOS A and levels of service on the Pleasant Street approach are expected to remain at LOS F for future No-Build conditions. The analysis results are based on the assumption of random arrivals on the main street. The intersection should still function effectively because of the nearby signal at Manley Street, which will create gaps in traffic on West Center Street, allowing vehicles to exit Pleasant Street and the park-and-ride lot driveway.

Mt. Pleasant Street, New Bedford—At the intersection of Mt. Pleasant Street and the park-and-ride driveway in New Bedford, no geometric or traffic control changes are proposed under future 2030 conditions. Weekday morning and evening peak hour levels of service are expected to remain the same under future volume conditions, operating at LOS C or better. The intersection will function effectively with brief spikes in traffic exiting the park-and-ride lot when buses arrive.

Whale's Tooth, New Bedford—Access to the proposed Whale's Tooth park-and-ride facility in New Bedford will be provided via a new driveway on Acushnet Avenue. Traffic volumes on Acushnet Avenue

were projected to 2030 by applying an annual growth rate. Traffic volumes entering and exiting the main park-and-ride entrance in the peak hour periods were estimated based on the lot being at full capacity and 25 percent of daily users arriving during the morning peak hour and departing during the evening peak hour. The results of the capacity analysis indicate that LOS for vehicles entering and exiting the park-and-ride will be LOS B or better during each of the peak hours.

Intersections (Rail Station Areas)

New Bedford—No-Build conditions in New Bedford were analyzed for the two station locations proposed in New Bedford. These stations would serve both the Whittenton and Stoughton Alternatives:

- Whale's Tooth
- King's Highway

Intersections near these station locations were analyzed for the No-Build condition. The access to an expanded park-and-ride facility on Mount Pleasant Street was also analyzed for the No-Build Alternative.

The Whale's Tooth Station would be located east of Route 18 and north of Route 6 near the downtown and the waterfront. The 2030 No-Build traffic volume projections for the Whale's Tooth Station area are shown in Figures 4.1-28 and 4.1-29. Table 4.1-35 provides a comparison of traffic operations between No-Build and Existing Conditions. Under No-Build conditions, there are minor or no changes in LOS projected at the signalized intersections and most of the unsignalized intersections analyzed for the Whale's Tooth station location. One unsignalized location, Purchase Street at Route 18 SB ramp, currently operates at a LOS E during the evening peak hour and is expected to operate at the same LOS E under No-Build conditions. Three unsignalized locations are expected to decline from LOS E to LOS F during one peak hour; these include Coggeshall Street at North Front Street during the morning peak hour and Coggeshall Street at Purchase Street and Purchase Street at Weld Street during the evening peak hour.

Shaded rows reflect over capacity intersections (LOS = F)

The King's Highway Station would be located off King's Highway, east of the Route 140 interchange. The 2030 No-Build traffic volume projections for the King's Highway Station area are shown in Figures 4.1-30 and 4.1-31. With one exception, there are no changes in LOS projected at any of the locations analyzed for the King's Highway station location. The unsignalized intersection of King's Highway at Mount Pleasant Street operates at LOS E and LOS F, during the morning and evening peak hours respectively, under Existing Conditions. Under No-Build conditions, the intersection is expected to be signalized and to operate at LOS B and LOS E, respectively, during the morning peak and evening peak hours.

Freetown—No-Build conditions in Freetown were analyzed for one station location proposed in Freetown. This station would serve the Whittenton, and Stoughton Alternatives. The station would be located on the east side of South Main Street south of Route 24 Exit 9 between the Stop & Shop Distribution Center and the planned entrance to the Riverfront Business Park. The Riverfront Business Park is a proposed 1.7-million square foot commercial development on the west side of South Main Street south of the Stop & Shop Distribution Center.

Under Existing Conditions, the Freetown station study area consists of six unsignalized intersections. Under No-Build conditions, the two unsignalized locations at the Route 24 Exit 9 northbound and southbound ramps are expected to be signalized as mitigation for the Payne's Crossing project. A seventh location at Payne's Crossing driveway, which would also be signalized, has been added to the No-Build analyses. On the west side of South Main Street just south of Route 24 Exit 9, the Payne's Crossing development is proposed to include:

- A 167,000 square foot home-improvement warehouse store
- A 195,000 square foot discount superstore
- 15,000 square feet of other retail space
- 1,530 parking spaces

Proposed traffic mitigation for the Payne's Crossing project includes proposed improvements at Route 24 Exit 9:

- Widening a portion of South Main Street between the Payne's Crossing driveway and the northbound ramps intersection at Exit 9.
- Installing traffic signals at the South Main Street intersections with the Route 24 northbound and southbound ramps.

The 2030 No-Build traffic volume projections for the Freetown Station are shown in Figures 4.1-32 and 4.1-33. Table 4.1-36 provides a comparison of Existing and No-Build traffic operations.

One of the signalized intersections is projected to operate at a deficient LOS under No-Build conditions. South Main Street at the Route 24 northbound ramps is projected to operate at LOS E during the evening peak hour. Under the No-Build Alternative, two of the unsignalized intersections are expected to decline to LOS F during both the morning and evening peak hours. One additional unsignalized intersection is expected to decline to LOS F during the evening peak hour because of the expected increased volume of traffic on South Main Street resulting from already planned projects in the station vicinity.

Fall River—No-Build conditions in Fall River were analyzed for two proposed station locations. These stations would serve the Whittenton and Stoughton Alternatives:

- Fall River Depot
- Battleship Cove

The existing Fall River traffic volume networks were projected to create the 2030 No-Build condition traffic volume networks, which are depicted in Figures 4.1-34 and 4.1-35. A comparison of Existing and No-Build capacity analysis results for the Fall River station study areas are shown in Table 4.1-37. The Fall River Depot station site is located 1 mile north of downtown Fall River on North Davol Street at Pearce Street. Three signalized and four unsignalized intersections were analyzed for Fall River Depot Station. All are projected to experience no change in LOS from Existing Conditions to No-Build conditions.

NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

The proposed Battleship Cove station site would be on Ponta Delgada Boulevard west of Route 138 and south of I-195 and the Fall River Heritage State Park (Battleship Cove). Four unsignalized locations were analyzed for the Battleship Cove Station and all but one are expected to experience no change in LOS. The exception is Central Street at Davol Street where the westbound Central Street approach is projected to decline from LOS E to LOS F.

Taunton—No-Build traffic conditions in Taunton were analyzed for two station locations in the City of Taunton: Taunton Depot and Taunton.

A detailed No-Build traffic assessment was not prepared for the Dana Street Station, but potential impacts were addressed qualitatively through a screening analysis using traffic data for the nearby Downtown Taunton Station analyzed in the DEIS/DEIR and the 2035 Whittenton Electric boarding estimates provided by CTPS. See Section 4.1.4.2 for further information on the methodology and results of the screening analysis for the Dana St. Station.

The Taunton Depot station location is common to both the Stoughton and Whittenton Alternatives. It is accessible from Route 140 west of the Route 24 interchange. The Taunton 2030 No-Build traffic volume projections are shown in Figures 4.1-36 and 4.1-37 (the figures were developed for the DEIS/DEIR and also show the Downtown Taunton Station that has been replaced by the Dana Street Station under the Whittenton Alternatives). Table 4.1-38 presents the traffic operations comparison between Existing and No-Build conditions.

1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
4 average control delay for the critical movement, rounded to the nearest whole second, for unsignalized intersections
L = Left-turn; T = Through; R = Right-turn
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Five of the seven signalized intersections analyzed for this station location are expected to operate at acceptable levels of service during both peak hours under No-Build conditions. One location is expected to operate at acceptable levels of service during the morning peak hour but at LOS E during the evening peak hour, and one location is expected to operate at LOS E during both morning and evening peak hours. Route 140 at the Route 24 southbound ramps is expected to improve from LOS F to LOS E during the evening peak hour because of the planned improvements at that location described earlier. Route 140 at Hart Street will experience an increase in delay that would cause operations to decline slightly and operate at LOS E during both peak hour periods. No unsignalized intersections were analyzed for the Taunton Depot station location.

Under the Stoughton Alternative, the Taunton Station would be located on Arlington Street just north of Route 44 (Dean Street). Six of the seven signalized intersections analyzed for the Taunton station location are expected to operate at acceptable levels of service during both peak hours. The intersection of Route 44 at Longmeadow Road is projected to remain at LOS F during the morning peak hour and LOS E during the evening peak hour under No-Build conditions. LOS at the three unsignalized intersections analyzed is not expected to change from Existing Conditions to No-Build conditions.

Stoughton—The 2030 No-Build condition traffic volumes for the Stoughton Station study area were developed by applying a background growth rate of 5 percent to the existing traffic volumes. Vehicle trips associated with the projected No-Build condition growth in ridership at the station were then added to the base, and the traffic volume networks were developed. The No-Build condition morning and evening peak hour volume networks are depicted in Figure 4.1-38 and Figure 4.1-39.

To assess the change in traffic operations, roadway capacity analyses were conducted for the No-Build condition and compared to the existing conditions. The results of the signalized and unsignalized intersection capacity analyses for each of the study area intersections are summarized in Table 4.1-39 and Table 4.1-40. Complete traffic operations analysis results are provided in Appendix 4.1-K.

Table 4.1-39 Stoughton Station Signalized Intersection Capacity Analysis– No-Build Condition vs. Existing Conditions

		Existing Conditions			No-Build Condition		
Location	Period	v/c[1]	Delay[2]	LOS[3]	v/c	Delay	LOS

	Weekday Evening	0.90	49	D	0.94	60	E
Pleasant Street at Park Street/	Weekday Morning	0.92	36	D	0.96	45	D
Washington Street	Weekday Evening	0.79	24	C	0.83	27	C

Source: Synchro 7 (Build 773, Rev 8) software
1 volume-to-capacity ratio
2 average delay in seconds per vehicle
3 level of service

As shown in Table 4.1-39, there would be no change in level of service for the signalized intersection of Pleasant Street at Park Street/Washington Street under the No-Build condition. The intersection of Porter Street at Washington Street would continue to operate at an acceptable level of service during the morning peak hour but the level of service would decline from LOS D to LOS E during the evening peak hour.

As presented in Table 4.1-40 and Table 4.1-41, all locations operating at poor levels of service under existing conditions will continue to operate poorly in the future. Although a few of the unsignalized

intersections experienced a slight increase in delay under the No-Build condition, none are projected to degrade the level of service.

Easton—Traffic operations analyses under No-Build conditions were conducted at intersections near two proposed station locations in Easton:

- North Easton
- Easton Village

The North Easton station would be located west of Route 138 on the Easton-Stoughton town line. The Easton 2030 No-Build traffic volume projections are shown in Figures 4.1-40 and 4.1-41. As shown in Table 4.1-42, two signalized and two unsignalized intersections were analyzed and only one location is expected to change in LOS, from acceptable LOS D to LOS F under No-Build conditions. The two unsignalized locations are projected to continue operating at LOS F during both peak hours and the signalized intersection of Route 138 is projected to continue to operate at LOS F during the morning peak hour.

Raynham—The Raynham Park station site would be located on the west side of Route 138 just south of the former Raynham-Taunton Greyhound Park, now the Raynham Park Simulcast Center. Traffic operations at three signalized and six unsignalized intersections were analyzed for Existing Conditions. The Raynham 2030 No-Build traffic volume projections are shown in Figures 4.1-42 and 4.1-43. As shown in Table 4.1-43 and described earlier, under No-Build conditions three of the unsignalized

intersections along Route 138 are expected to be signalized, including the northbound and southbound I-495 ramps, and Center Street. All three of these intersections operate at LOS F as unsignalized intersections but are expected to operate at LOS C or better under signalization. The original three signalized intersections are expected to continue operating at acceptable levels of service. Both unsignalized Britton Street intersections with Route 138 are projected to operate at LOS F and the Wilbur Street intersection with Route 138 is expected to decline from LOS D to LOS E during both peak hours under No-Build conditions. The Raynham Park driveway is projected to decline from LOS E to LOS F during both peak hours.

4.1.4.2 Build Alternatives

Regional Transportation Impacts

This section evaluates the impact on regional transportation with regard to the four key criteria identified in Section 4.1.2 and as utilized in preceding alternatives analyses with regard to achieving the project purpose. They include positive and negative impacts on the ability of the transportation system

to meet projected ridership demand, the impact of an alternative on the quality of service of the transportation system as expressed in transit travel time, adherence to MBTA service delivery policy and reliability of the transportation system, impact on VMT and the impact of an alternative on regional mobility (i.e. the connectivity among transportation services). Ridership projections were developed by CTPS based on established methodologies for transportation projects. Documentation of the ridership modeling methodology is provided in Appendix 3.2-G and 3.2-H.

Ridership Demand

To conservatively determine the effects of the Build Alternatives on the regional highway network, the transit ridership projections for the No-Build (Enhanced Bus) Alternative and the Build Alternatives were modeled and compared. The No-Build ridership projections reflect the Enhanced Bus boardings and alightings. The Build Alternative ridership projections reflected both boardings and alightings for the existing regional bus and proposed commuter rail services. To determine the benefit (Build vs. No-Build), the No-Build Enhanced Bus Alternative ridership was subtracted from the Build Alternative ridership to determine the amount of additional transit ridership that the Build Alternatives are projected to attract. All boarding and alighting projections were calculated for three-hour morning and evening peak periods.

Ridership demand was evaluated to determine how well an alternative would be able to meet existing and future demand for public transportation between Fall River/New Bedford and Boston. In order to estimate overall transit demand for the region, an optimal transit system with no constraints such as construction costs or environmental impacts would have to be simulated. While this optimal transit demand has not been quantified, demand was measured in terms of the number of daily work-related trips between South Coast communities and Boston. For this screening analysis, transit demand was based on 2000 Journey-to-Work (JTW) data.

Total service to the South Coast region was considered the total station boardings as projected for each alternative in addition to boardings at existing commuter bus services, which is anticipated to continue to operate with the South Coast Rail project in place. According to the JTW data, the number of daily work trips from the South Coast region to Boston is approximately 8,000. The ability of the alternative to meet possible future ridership potential was calculated as the percent of met ridership demand.

As shown in Table 4.1-44, the rail alternatives would result in 3,930 to 4,570 daily boardings at the new stations. Private bus service boardings would decline substantially to 1,100 to 1,350 (compared to 6,000 in the 2035 No-Build condition) as a result of the diversion of passengers to the new rail option. When the rail ridership and remaining bus ridership are considered together, the alternatives meet 65.5 to 71.0 percent of the demand for approximately 8,000 work trips from the South Coast region to Boston.

Due to a faster travel time to Boston, the Stoughton Alternatives achieve greater ridership in the Southern Triangle than the Whittenton Alternatives. For example, the Stoughton Electric would have 840 daily boardings at Fall River Depot compared to 750 under the Whittenton Electric Alternative. The Whittenton Alternatives ridership is also less than the Stoughton Alternatives because the Whittenton alignment does not include the Taunton Station, which has 670 daily boardings under the Stoughton Electric Alternative. The Whittenton Alternative station closest to downtown Taunton (Dana Street) has substantially lower ridership (320 daily boardings under the electric alternative). The Whittenton Electric Alternative boardings at Raynham Park (520) would be higher than under the Stoughton Electric (430), because in the absence of Taunton Station, some riders would proceed to Raynham Park rather than Dana Street.

Table4.1-44 Daily Ridership Demand by Alternative (2035)

Name	New Station Boardings*	Boardings at Existing Commuter Bus Services	Total Service to South Coast Region	Percentage of Met Ridership Demand[1]
Stoughton Electric Alternative	4,570	1,100	5,670	70.9%
Stoughton Diesel Alternative	4,430	1,250	5,680	71.0%
Whittenton Electric Alternative	4,040	1,200	5,240	65.5%
Whittenton Diesel Alternative	3,930	1,350	5,280	66.0%

1 Total Service to South Coast region divided by the number of daily work trips from the South Coast region to Boston (approximately 8,000)
* Relocated Stoughton Station not considered "new"

The difference in ridership between the electric and diesel versions of the alternatives is small, with the diesel alternative rail ridership at new stations being approximately three percent lower than the corresponding electric alternative due to slightly longer travel times. Despite having lower rail ridership, the Stoughton Diesel Alternative has the highest total service to the South Coast Region when considered together bus service (although the difference from the electric version is negligible—10 boardings).

Quality of Service

The following two sections evaluate how well each alternative provides a transit service. It focuses on two factors: travel time and reliability. Travel time measures how quickly an alternative would be able to get a passenger from the South Coast region into Boston and reliability measures how often that service would be on time and, therefore, how dependable the service would be to the passengers who ride it. An alternative that does not improve the quality of transit services over the existing services provided in the region provides no functional benefit to the communities. Quality of service is assessed based on commuting time, reliability, comfort, convenience and safety. For the purposes using quantifiable criteria, only run time and reliability are used as subcriteria.

Travel Time—Since New Bedford/Fall River commuters currently rely on cars and private bus services, an improved quality of service would have to provide a comparable or competitive *travel time* and improved *reliability* with respect to existing commuter options during peak commuting periods. The average commuting time by car during rush hour in 2009 was 90 minutes and travel time by car is projected by CTPS to deteriorate further to 100-120 minutes under the No-Build scenario. There would be no measurable change in travel time by car under the Build Alternatives because due to the saturated nature of the corridor, any trips that shift to rail with the Build Alternatives would be replaced and would result in no change to travel time by car. Travel time for the rail alternatives was based on rail operations analysis,[12] which identified the segments of the rail corridors that would operate at top speed as well as segments where speed is constrained due to speed restrictions, geometry, vehicles, power mode, dwell times and number of stations and civil restrictions. Each commuter rail alternative has two overall run times: one for electric locomotives and one diesel locomotives. The primary factor

[12] Capacity Utilization Analyses Technical Memorandum, Systra USA, November 17, 2008.

differentiating the travel time performance of the electric vs. diesel option is the greater acceleration time for diesel trains.

Table 4.1-45 summarizes travel time provided by each alternative and shows the reduction in travel time compared to the 2035 No-Build travel time by automobile in the peak period.

Table 4.1-45 Average Travel Times by Alternative (New Bedford to South Station Peak Period)

Name	Rail Travel Time (min)	Change from 2035 Auto Travel Time (100 minutes)
Stoughton Electric Alternative	77	-23
Stoughton Diesel Alternative	82	-18
Whittenton Electric Alternative	84	-16
Whittenton Diesel Alternative	89	-11

The Stoughton Electric Alternative achieves the fastest travel times (77 minutes between New Bedford and Boston during the peak period). The Stoughton Diesel Alternative takes approximately 5 minutes longer than the electric alternative to travel the same route because of the additional time diesel locomotives need to accelerate from the stations and the lower maximum speed of the diesel trains.

The longer route, and the lower speed needed to maintain safety on the sharp curves in Taunton under the Whittenton Electric Alternative, results in a total travel time approximately seven minutes longer than the Stoughton Electric Alternative (84 minutes compared to 77 minutes). The Whittenton Diesel Alternative takes 5 minutes longer to travel from New Bedford to Boston than the Whittenton Electric Alternative and has the longest travel time of the rail alternatives.

Service Delivery Policy

While an alternative might offer many benefits for the transit system in the South Coast region, it may be an unattractive service for the communities it is designed to serve because it offers too few trips. In order to maintain acceptable service, the MBTA has established a Service Delivery Policy[13] to ensure it provides quality transit services that meet the needs of the riding public. The minimum frequency of service levels provides the guidelines by which the MBTA maintains accessibility to the transportation network within a reasonable waiting period. The minimum frequency of service standards is the minimum frequency that must be maintained in a service. Commuter Rail minimum frequencies should provide 3 trips in a peak direction during the AM and PM peak periods.[14]

The Stoughton and Whittenton Alternatives (electric and diesel variants) would all meet the minimum service delivery policy standard.

Vehicle Miles Traveled

VMT is an important gauge for an alternative’s transportation system benefits. VMT measures the extent of motor vehicle operation or the total number of vehicle miles traveled within the study area on given day. This particular measure quantifies how many miles of travel would be removed from the regional roadway network by commuters who elect to travel by train or bus rather than drive. This

[13] Massachusetts Bay Transportation Authority, *Service Delivery Policy*, MBTA Board of Directors approved January 14, 2009.
[14] Between LIRR, MNRR, MBTA, and METRA, the average service provided is 2.9 peak period trains.

reduction in driving has several environmental benefits, notably, cleaner air and a reduction in greenhouse gas emissions. Fewer cars on the road also ease congestion along highway corridors. The alternative with the greatest VMT change (reduction) receives the highest score under this criterion.

Table 4.1-46 summarizes the daily reduction in VMT provided by each alternative based on updated CTPS projections for 2035 and how the alternatives score against each other with regard to meeting the project purpose to reduce VMT.

Table 4.1-46 Regional VMT Reductions by Alternative (2035, Auto and Bus Transit)

Name	VMT Reduction (daily miles)
Stoughton Electric Alternative	(-255,932)
Stoughton Diesel Alternative	(-240,348)
Whittenton Electric Alternative	(-201,232)
Whittenton Diesel Alternative	(-186,306)

The Stoughton Electric Alternative achieves the greatest reduction in daily VMT of all the alternatives, approximately 54,700 VMT per day greater than the Whittenton Electric Alternative. The Stoughton Diesel Alternative has the second greatest VMT reduction, approximately 6.1 percent less than the Stoughton Electric Alternative. With the longest travel time and lowest ridership, the Whittenton Diesel Alternative is also the least effective of the rail alternatives in reducing regional VMT, although it still provides substantial benefits (reduction of 186,306 VMT per day).

Regional Mobility

The following sections discuss the number of interregional links provided by each alternative as an indication of how well each alternative meets the project purpose to improve regional mobility. As all the alternatives provide a connection from Fall River and New Bedford to Boston, an alternative will be considered more favorable if it also enhances mobility between points within the region. An interregional link is a link that provides a one-seat ride from one municipality to another. Connections within a municipality were not counted. For instance, New Bedford, which would accommodate two stations, would provide a one-seat ride from Whale's Tooth to King's Highway. However, this connection was not considered an improvement to regional mobility as it is contained within New Bedford.

The Stoughton and Whittenton Alternatives are equivalent in terms of meeting the regional mobility project purpose—both alternatives provide 41 interregional links.

Table 4.1-47 highlights the interregional links provided by the Stoughton and Whittenton Alternatives.

Table 4.1-47 Interregional Links–Stoughton and Whittenton Alternatives[1]

1 Inter-municipal connections not included.

Impacts to Freight Operations

An improved infrastructure would improve the future of freight operations in the South Coast region. The current lines operate at a class 3 or higher, only allowing for very slow speed operations. With the infrastructure improvements that will come as part of the South Coast Rail passenger service the growth of freight operations could certainly occur if properly planned.

By far the most difficult part of future freight operations will occur in and around Weir Junction. The Massachusetts Coastal Railroad (Mass Coastal) handles this labor intensive switching in this area and has noted that this is practically a full time (5 days per week) operation, which could grow even more successful with more infrastructure improvements. In addition the track geometry here only allows for slow speed operations. The current and even future proposed freight operation splits the proposed main line (under the Stoughton Alternative). This is because two of the current three Mass Coastal customers are on the east side of the proposed main line, while the third and largest of their shippers is on the west side. This sets up conflicts between operating passenger trains and freight trains during the same period of time.

The need to somehow segregate freight and passenger operations will be critical to the success of both. Under the original design work completed in 2001 new infrastructure was proposed for this area. It consisted of new infrastructure in the Taunton area that would support freight interchanges and "run-arounds"[15] on dedicated freight tracks between Cotley and Weir Junctions. This includes an interchange track at Weir Junction, a diamond crossing to access the New England Refrigerated along with freight set-off/run-around tracks located between Hart Street and Cotley Junction. The main line freight track (currently known as the Attleboro Secondary) will exist adjacent to the MBTA main line between Weir Junction and Hart Street, continuing on to Cotley Junction and Middleborough secondary or continue down to New Bedford/Fall River at Myricks Junction.

[15] A run-round loop (or run-around loop) is a track arrangement that enables a locomotive to attach to the opposite end of the train. This process is known as "running round a train". It is commonly performed to haul wagons onto a siding, or at a terminal station to prepare for a return journey

The MBTA's proposed passenger train operation will use two tracks from a point just south of Hart Street, through and including Cotley Junction. Freight trains will operate on a dedicated freight track to the west side of the passenger tracks. Freight trains wishing to gain access onto the Middleborough Secondary will wait just north of Cotley Junction for clear operating windows to cross the proposed passenger tracks. Freight trains wishing to head south to either New Bedford or Fall River will also wait here until any passenger trains in these sections have cleared. It should be noted that while the third track's primary purpose is to store/hold freight trains, it will be designed and constructed to support passenger trains so as to maintain operational flexibility.

Cotley Junction is configured to support the direct movement of trains between Middleborough and Attleboro. A freight train coming from either Fall River or New Bedford will need to access the freight track at Cotley Junction before moving on to either Attleboro or Middleborough. This should not present a problem for the freight operations as shuttle type service makes sense from both of these points. However, it must be noted that interchanges between New Bedford and Fall River with the Middleborough line must occur via a reverse direction movement at Taunton. These maneuvers will predominantly depend upon the Cotley Freight Runaround track. It should be noted that the Cotley Freight Runaround should not be used to set off (store) freight cars or freight operations will be severely impacted.

Possible Benefits of the Future Infrastructure

Future local freight switching operations from or via Taunton must support service to three potential territories:

- the Stoughton line;
- Taunton area customers; and
- the New Bedford and Fall River branches.

Freight service to New Bedford and Fall River may operate one of three different ways:

- from Framingham or Readville via Attleboro and Cotley Junction proceeding directly to New Bedford or Fall River;
- from Middleborough, making a run-around move via the proposed Cotley Freight Runaround and then proceeding to New Bedford or Fall River; or
- via Canton Junction, proceeding directly via Taunton to New Bedford or Fall River.

Presently, the only access to the remaining active freight rail customers on the existing Stoughton Branch is via the Northeast Corridor through Canton Junction. The MBTA may or may not grant a freight carrier access to the Canton area through the proposed reconstructed line between Longmeadow Road, Taunton, and the present location of end-of-track in Stoughton. Then railcars consigned to or released by customers located on the line between Taunton and Stoughton could be set-off/switched on the proposed Interchange Track at Weir Junction. Then they would be forwarded via either Middleborough or Attleboro, thence to Beacon Park Yard or Framingham.

Daytime rail freight service on the line segment between Longmeadow Road, Taunton and Stoughton is possible, but not practical. The density of proposed passenger rail service indicates that adequate "windows" for daytime freight operations exist. However, more opportunities exist due to the future track infrastructure. These include the short sidings at Longmeadow Road, Raynham, and the longer siding at North Easton.

Nighttime will provide the freight carriers the best opportunity to complete their rail operations daily. The existing MBTA operations begin at 5:38 AM when the first westbound equipment move reaches Canton Junction from Boston and end at midnight. Proposed layover terminals at Freetown and New Bedford will eliminate these early morning and late night MBTA train movements thereby further increasing the window of opportunity for freight service.

Taunton area customers, including the Rand McNally plant and Mass Coastal's existing customers located on the portion of the New Bedford Line known as the Dean Street Industrial Track, could be served by a switcher based at Taunton. This switcher would also perform the interchange with a line-haul train at Taunton.

Freight service on the New Bedford and the Fall River branches south of Myricks Junction could be a daytime operation. Mid-day MBTA service frequency to each branch is on a 120-minute interval as proposed. This is enough time for a freight train to operate between Fall River and Freetown or Myricks on the Fall River branch. If required the train could pull into one of the proposed Controlled Passing Sidings to clear the main track for an MBTA passenger train. Likewise, this is true for a freight train to operate between Myricks and the Watuppa Branch junction point located just north of New Bedford. On the New Bedford route, since the freight operation is uniquely separated from the freight service operations between Myricks and New Bedford can occur at any time.

The potential of the rail alternatives for impacts to freight operations was investigated by exploring various operating scenarios, as described below.

- A line-haul train originates at Framingham, Massachusetts on the existing CSX Boston Line (and MBTA's Worcester Line route). The train would operate to Attleboro via Mansfield, reverse at Attleboro and proceed to Middleborough via Cotley Junction, stopping in Taunton as necessary to pick up and set-out cars for the Mass Coastal Railroad at Weir Junction. The train would deliver the rest of its cars to Middleborough. Since this train needs access from the Northeast Corridor the train must operate at night between Mansfield and Attleboro.

- A switcher and crew would be called at Middleborough every weekday morning as demand dictated and would operate to Taunton, serving any local customers en route. The train would include cars for either the New Bedford line or the Fall River branch. The train would reverse at Taunton using the Cotley Freight Runaround. When MBTA traffic permits, it would proceed to the New Bedford line or to the Fall River Branch via Myricks Junction.

- All cars collected by the trains operating as per (2) above and cars being collected by the Mass Coastal Railroad along the Middleborough main line would be brought back to an expanded Middleborough yard to be re-assembled into a nighttime line-haul train. This train could then proceed through to Framingham (or perhaps to Beacon Park Yard via the Middleborough/Braintree and the South Station Wye.

- A nighttime Mass Coastal Railroad switch engine and crew would locally deliver the cars left on the Weir Junction Interchange Track by the line-haul train as described at Step (1) above, and return all outgoing cars to the interchange track for pickup. This switch engine might, or might not, have rights to operate as far north at Stoughton. This would depend upon whether this access is negotiated with, and granted by, the MBTA and CSX.

Assuming adequate capacity of the Weir Junction Interchange Track, none of the operational changes would require storage of freight cars on the proposed Cotley Freight Runaround. Should additional capacity be needed beyond that provided by the Weir Junction Interchange Track, the excess cars could be placed on the Runaround Track for collection by the line-haul train the same night. Any daytime switching operations in Taunton would be limited to run-around moves at the Cotley Runaround Track and potentially switching the Rand McNally plant located adjacent to Route 140 near Cotley Junction. Freight customers requiring service at Taunton but lacking a private industrial siding would take deliveries at one of the existing lngell Street spurs.

As described above, feasible scenarios could be developed that would enable co-existence of freight operations and the rail alternatives without impacting freight operations. While during the construction process of the proposed rail alternatives, freight operations would be temporarily impacted, the operation of the rail alternatives would not interfere with freight operations. The permanent long-term infrastructure improvements to the rail network associated with the rail alternatives would also benefit freight operations.

Traffic Operations Analysis

Regional Freeway Benefits

As discussed in Section 4.1.2.3, regional freeway benefits were conservatively assessed based on ridership for the Rapid Bus Alternative. The regional freeway benefits of the Stoughton and Whittenton Alternatives would be greater than the results discussed below.

As shown in **Table** 4.1-48, the four freeway segments analyzed on Route 24 between I-495 and I-93/Route 128 would see an improvement in LOS in the Build condition. During the morning peak hour all four segments would see LOS in the peak northbound direction improves from LOS E to LOS D. The two segments of Route 24 south of I-93 and south of Pond Street would experience similar improvement in the southbound direction in the evening peak hour. Because of these changes, all Route 24 freeway segments from I-495 to I-93 in the Build condition will operate at LOS D or better. There would also be improvements on I-93. I-93 south of Furnace Brook Parkway would also improve in the northbound direction in the morning peak hour from LOS F to LOS E. The two segments of I-93 south of Furnace Brook Parkway and south of Route 3 would improve from LOS E to LOS D. Under the Build condition, the two segments of Route 140 that were analyzed would continue to operate at LOS C or better.

Table 4.1-48 Freeway Capacity Analyses Summary, 2030

Traffic Impacts Associated with Grade Crossings

This section provides an evaluation of the transportation impacts associated with the public grade crossings that would be in service along the South Coast Rail project alternatives. Figures 4.1-44 through 4.1-53 present all of the crossing locations for each rail corridor with each crossing's recommended treatment (grade separation, closure, or at-grade crossing). The figures also show the grade crossings in relation to primary emergency vehicle routes, emergency response service providers, and schools. A preliminary assessment of the rail corridors identified 52 existing active public grade crossings. Along the Fall River Secondary (common to all alternatives), four public crossings would be recommended for closure. The Stoughton Alternative would result in 43 active public grade crossings, and the Whittenton Alternative would result in 50 active public grade crossings. Transportation impacts at the proposed public grade crossings were assessed. Based on the traffic and safety analysis conducted, it is recommended that each location would be suitable for public use equipped with a combination of new, state of the art, Automatic Highway Crossing Warning (AHCW) systems and minor geometric modifications such as driveway reconfiguration, driveway closures, vegetation clearing and utility pole relocations. The delay and queue technical analysis for all locations can be found in Appendix 4.1-J.

Southern Triangle Grade Crossings Impacts (Common To All Rail Alternatives)

The majority of grade crossings in the Southern Triangle are projected to be closed only three to four times an hour, or approximately five to seven percent of the peak hour as a result of the introduction of commuter rail service. The Taunton grade crossings would be closed six times an hour, or ten percent of the peak hour. A description is provided below of the effects on traffic conditions at grade crossings in the Southern Triangle resulting from all rail alternatives.

New Bedford Grade Crossings (3) (all Rail Alternatives)—Three grade crossings in New Bedford currently carry active freight traffic and would be upgraded to accommodate the proposed commuter rail service.

- **Samuel Barnet Boulevard**. Samuel Barnet Boulevard serves mainly industrial park-related traffic and the minor queuing anticipated would not affect the traffic operations of these driveways.

Table 4.1-49 shows the traffic volumes and average delay expected along Tarkiln Road and Nash Road where more substantial queuing impacts may occur. An overview of the conditions at both roads is provided below.

Table 4.1-49 New Bedford Grade Crossings–Traffic Volumes[1] and Average Delay (All Rail Alternatives)

Crossing	Traffic Volume (vpd)	AM Peak Volume	PM Peak Volume	Queue Length (feet)	Average Delay (seconds)
Tarkiln Hill Road	34,000	815	1285	550	51
Nash Road	14,900	510	745	325	42

Source: MassDOT Highway Division supplemented by counts.
1 2030 Build Condition

- **Tarkiln Hill Road**. On Tarkiln Hill Road, a calculated queue length of 550 feet and average delays of 51 seconds are projected during peak periods. Existing vehicle queues on the Tarkiln Hill Road eastbound approach to Church Street extend over the grade crossing and beyond the intersection of King's Highway at Stop & Shop. The existing vehicle queues currently impact traffic at two unsignalized intersections (Tarkiln Hill Road at King's Highway and Tarkiln Hill Road at Worcester Street/Park Avenue) as well. Grade separation was considered at this location but cannot be achieved due to both horizontal and vertical curvature constraints and the crossing's proximity to the proposed King's Highway Station platform. Tarkiln Hill Road is proposed to be closed north of its intersection with King's Highway. Traffic along Tarkiln Hill Road would be rerouted through the Stop & Shop driveway intersection. As part of the proposed project, traffic signal preemption is recommended at the intersections of King's Highway and Stop & Shop driveway and Tarkiln Hill Road at Church Street to clear vehicle queuing that extends over the tracks when a train is approaching. Since queues from the adjacent intersections are projected to extend to or over the track location, the need for pre-signals at this grade-crossing, to prevent vehicles from queuing back to the grade crossing during the pre-emption period, will be evaluated as part of the preliminary design phase of the project.

- **Nash Road**. On Nash Road, a calculated queue length of 325 feet and average delays of 42 seconds are projected during peak periods. Existing vehicle queues on the Nash Road westbound approach to Church Street back up over the grade crossing. The vehicle queues could affect traffic at the unsignalized intersection of Nash Road and King Street and at driveways within 325 feet of the crossing. As part of the proposed project, traffic signal preemption is recommended at the intersection of Nash Road and Church Street to clear vehicle queues that extend over the tracks when a train is approaching. Since projected queues from the adjacent intersections are projected to extend to or over the track location, the need for pre-signals at the Nash Road eastbound approach to the grade-crossing will be evaluated as part of the preliminary design phase of the project.

Fall River Grade Crossings (None)—There are no at-grade crossings in Fall River. All major grade crossings within Fall River are grade-separated and all remaining private roadways crossings are expected to be closed.

Freetown Grade Crossings (11) (All Rail Alternatives)—Eleven existing public grade crossings in Freetown currently carry active freight traffic and would be upgraded to accommodate the proposed commuter rail trains. Seven of these crossings are expected to cause minor delays and have little impact on the surrounding roadways.

- **Chace Road**. On Chace Road, the maximum queue lengths and average delays are expected to be minimal. The sand and gravel operation driveway and the residential driveway could be affected by the vehicle queues at the crossing; however, delays are expected to be minimal. The existing driveway on the west side of the crossing may need to be reconfigured or closed.

- **Braley Road**. The maximum queue lengths and average delays at Braley Road are expected to be minimal. The driveway located about 75 feet west of the tracks on the north side of the road is expected to be affected by vehicles queued at the crossing; however, delays would be minimal. On East Chipaway Road, the maximum queue lengths and average delays are expected to be moderate. The residential driveway located approximately 20 feet east

of the tracks may be affected by vehicles stopped at the crossing; however, delays would be minimal.

- **Elm Street**. The maximum queue lengths and average delays along Elm Street are expected to be minimal. The driveways located 50 feet west and 120 feet east of the tracks would be impacted by the vehicles queued at the grade crossing; however, delays would be minimal.

- **High Street**. The maximum queue lengths and average delays at High Street are expected to be minimal. The residential driveway located on the east side of the tracks and Alexandra Drive on the west side of the tracks may be impacted due to the anticipated queued vehicles at the grade crossing; however, delays would be minimal.

- **Copicut Road**. On Copicut Road, the maximum queue lengths and average delays are expected to be minimal. The dirt driveway immediately east of the tracks may be impacted by vehicle queues; however the driveway serves very few vehicles and motorists would not likely be affected.

- **Beachwood Road**. The crossing along Beachwood Road is located approximately 150 feet east of the intersection of Route 79 at Beachwood Road. The safety implications of this proximate crossing require the Beachwood Road crossing to be closed and a cul-de-sac would be constructed on the east side of the tracks. Residential traffic destined to Route 79 would divert to Malbone Road. Since there is only one home on Beachwood Road, impacts of additional traffic on Malbone Road should be minimal.

- **Richmond Road/Route 79 (North)**. Richmond Road/Route 79 (North) is expected to have minimal queue lengths and average delays. The residential driveways located on both sides of the tracks would be slightly affected by the vehicles queued at this crossing.

Table 4.1-50 shows the traffic volumes and average delay at the remaining three grade crossings, which are expected to experience the most substantive delay.

Table 4.1-50 Freetown Grade Crossings—Traffic Volumes[1] and Average Delay (All Rail Alternatives)

Crossing	Traffic Volume (vpd)	AM Peak Volume	PM Peak Volume	Queue Length (feet)	Average Delay (seconds)
Forge Road (North)	1,200	80	80	50	31
Richmond Road (South)	4,900	215	200	100	34
Forge Road (South)	3,400	205	175	100	33

Source: MassDOT Highway Division supplemented by counts.
1 2030 Build Condition

- **Forge Road (North)**. The Forge Road (North) crossing occurs immediately north of the intersection of Richmond Road and Forge Road. The safety implications of this proximate crossing require the Forge Road (North) crossing to be closed and a cul-de-sac would be constructed on the west side of the tracks just west of the existing stream. Residential traffic currently using Forge Road to access Richmond Road would be diverted to Locust Street. Since Forge Road is a small residential street serving about 25 homes, traffic impacts on Locust Street due to this diversion are expected to be minimal. The southern leg of the

Richmond Road/Forge Road intersection would remain open to traffic. Queuing impacts are not expected along this section of Forge Road.

- **Richmond Road/Route 79 (South)**. On Richmond Road/Route 79 (South), a calculated queue length of 100 feet and average delays of 34 seconds are projected during peak periods. The residential driveway west of the tracks would be affected by any vehicles queued at the crossing and may need to be reconfigured to ensure vehicles exiting the driveway will be adequately protected by the proposed crossing signalized gate.

- **Forge Road (South)**. On Forge Road (South) a calculated queue length of 100 feet and average delays of 33 seconds are projected during peak periods. There may be impacts to driveways on both sides of the crossing due to the anticipated queued vehicles at the grade crossing.

Lakeville Grade Crossing (1) (All Rail Alternatives)—

- **Malbone Street**. The only public grade crossing in Lakeville, Malbone Street, currently carries active freight traffic and would be upgraded to accommodate the proposed commuter rail trains. The maximum queue lengths and average delays at this location are expected to be minimal.

Berkley Grade Crossings (5) (All Rail Alternatives)—All five grade crossings in Berkley (Cotley Street, Padelford Street, Myricks Street (Route 79), Mill Street, and Adams Lane) currently carry active freight traffic. Crossings at these locations would be upgraded to accommodate the proposed commuter rail trains.

- **Cotley Street and Padelford Street**. On Cotley Street and Padelford Street, the maximum queue lengths and average delays are expected to be minimal and there would be no impacts to driveways or intersections due to this grade crossing.

- **Myricks Street (Route 79)**. On Myricks Street (Route 79), maximum queue lengths and average delays are also expected to be minimal. Left turns from Grove Street could be affected by vehicles queued at the crossing. Grove Street could be delineated to accommodate separate left and right turn lanes to mitigate any delays. Vehicle queues at this crossing would also impact driveways on the west side of the crossing. Gates and locks are proposed to access the utility road on the northwest corner of the crossing.

- **Mill Street and Adams Lane (private)**. The Mill Street and Adams Lane private crossings are proposed to be closed.

Taunton Grade Crossings (2) (All Rail Alternatives)—Two public grade crossings on the New Bedford Main Line corridor are located in Taunton. Both the Ingell Street and Hart Street crossings currently are active crossings with freight train activity. These crossings would be upgraded to accommodate the proposed commuter rail trains. Table 4.1-51 shows the traffic volumes and average delay at these grade crossings.

Table 4.1-51 Taunton Grade Crossings—Traffic Volumes[1] and Average Delay

Crossing	Traffic Volume (vpd)	AM Peak Volume	PM Peak Volume	Queue Length (feet)	Average Delay (seconds)
Ingell Street	7,500	435	460	200	38
Hart Street	13,000	460	430	200	38

Source: MassDOT Highway Division supplemented by counts.
1 2030 Build Condition

- **Ingell Street**. Calculated queue lengths of 200 feet and average delays of 38 seconds are projected at Ingell Street during peak periods. Vehicle queues at this crossing will affect driveways on both sides of the crossing. The driveway immediately to the west of the crossing is proposed to be closed. There are no anticipated impacts to any intersections due to queued vehicles at the grade crossing.

- **Hart Street**. On Hart Street, a calculated queue length of 200 feet and average delays of 38 seconds are projected during peak periods. Alegi Avenue and driveways located within 250 feet of the tracks would be impacted by minor delays associated with the anticipated queues at the grade crossing.

Stoughton Alternatives Grade Crossing Impacts

The Stoughton Alternatives will require gates at grade crossings within Taunton, Raynham, Easton, Stoughton and Canton to be closed approximately six times an hour, or approximately 10 percent of the peak hour.

Taunton Grade Crossings (2) – Stoughton Alternative—Two public grade crossings associated with the Stoughton Alternative are located in Taunton. One grade crossing would be reactivated as part of the Stoughton Alternative (Longmeadow Road). The other grade crossing, Dean Street (Route 44) is currently active for freight rail only with frequencies of a few times a week. As described in Section 4.1.3.4, between Weir Junction and Winter Street in Taunton, existing train frequency is approximately two roundtrip freight trains (four total trips) per month. Train frequency near Ingell Street at Weir Junction ranges from three to five roundtrip freight trains (six to ten total trains) per week. There is no existing train frequency along the unused rail alignment from Stoughton station to Winter Street in Taunton. The Dean Street crossing would be upgraded to accommodate the proposed commuter rail trains. Table 4.1-52 shows the traffic volumes and average delay at both grade crossings. The Thrasher Street crossing is currently grade separated and is therefore not discussed in this section.

Table 4.1-52 Taunton Grade Crossings—Traffic Volumes[1] and Average Delay Stoughton Alternatives

Crossing	Traffic Volume (vpd)	AM Peak Volume	PM Peak Volume	Queue Length (feet)	Average Delay (seconds)
Winter Street/Longmeadow Road	13,300	510	635	275	41
Dean Street	33,500	910	880	875	109

Source: MassDOT Highway Division supplemented by counts.
1 2030 Build Condition

- **Longmeadow Road**. On Longmeadow Road, a calculated queue length of 275 feet and average delays of 41 seconds are projected during peak periods, and may affect the commercial driveways on both sides of the crossing. Existing driveways and parking areas immediately adjacent to the crossing would be reconfigured and/or closed.

- **Dean Street**. On Dean Street, a calculated queue length of 875 feet and average delays of 109 seconds are projected during peak periods, which may affect the driveways on both sides of the crossing and traffic operations at the adjacent Arlington Street intersection. This active grade crossing currently experiences similar (albeit infrequent) delays when freight trains service the various industrial uses in Taunton. As part of the proposed project, new traffic signal equipment and preemption phasing is recommended at the intersection of Dean Street and Arlington Street. The new signal layout will be coordinated with the AHCW system and preemption installed to adequately clear the vehicles queuing onto the tracks when a train is approaching. The intersection may also need to be reconfigured to safely direct pedestrians to the appropriate route.

Raynham Grade Crossings (6)—Six public grade crossings are located in Raynham. Five of the crossings are currently inactive and would be reactivated as part of the Stoughton Alternatives. The sixth grade crossing, across Broadway (Route 138), is projected to have relatively high traffic volumes (27,400 vehicles per day and 1,415 and 1,425 vehicles during the AM and PM peak), which would result in relatively long queues (700 feet) and delays (63 seconds). These queues and delays could affect Center Street and Britton Street traffic as well as numerous driveways in the proximity of the crossing. This public grade crossing would therefore be converted to a grade-separated crossing to minimize traffic impacts along this section of Route 138. Table 4.1-53 shows the traffic volumes and average delay at the five remaining grade crossings.

Table 4.1-53 Raynham Grade Crossings—Traffic Volumes[1] and Average Delay Stoughton Alternative

Crossing	Traffic Volume (vpd)	AM Peak Volume	PM Peak Volume	Queue Length (feet)	Average Delay (seconds)
Elm Street	1,900	100	65	50	32
Carver Street	6,800	335	385	175	37
Britton Street	1,300	65	65	50	31
King Phillip Street	4,100	295	350	150	36
East Britannia Street	4,700	335	415	175	37

Source: MassDOT Highway Division supplemented by counts.
1 2030 Build Condition

- **Elm Street**. On Elm Street, a calculated queue length of 50 feet and average delays of 32 seconds are projected during peak periods and could affect a residential driveway located 35 feet to the west of the crossing.

- **Carver Street**. A calculated queue length of 175 feet and average delays of 37 seconds are projected on Carver Street during peak periods and could affect a residential driveway located 100 feet west of the crossing. There is a culvert that may need to be reconstructed in proximity to this crossing.

- **Britton Street**. On Britton Street, a calculated queue length of 50 feet and average delays of 31 seconds are projected during peak periods, and may affect the residential driveways on both sides of the crossing.

- **King Phillip Street**. A calculated queue length of 150 feet and average delays of 36 seconds are projected at King Phillip Street during peak periods, and may affect residential driveways on both sides of the crossing. The driveway located adjacent to the tracks is currently within the railroad right-of-way for approximately 300 feet connecting with a property set back from King Phillip Street, and would need to be relocated outside of the railroad right-of-way to accommodate the proposed alignment.

- **East Britannia Street**. On East Britannia Street, calculated queue lengths of 175 feet and average delays of 37 seconds are projected during peak periods. Driveways and intersections along East Britannia Street are not expected to realize impacts due to the crossing.

Easton Grade Crossings (7) - Stoughton Alternatives—Seven public grade crossings are located in Easton. All of the crossings in Easton would be reactivated as part of the Stoughton Alternatives. Table 4.1-54 shows the traffic volumes and average delay at these grade crossings. The Main Street crossing is currently grade separated and is therefore not discussed in this section.

Table 4.1-54 Easton Grade Crossings—Traffic Volumes[1] and Average Delay Stoughton Alternatives

Crossing	Traffic Volume (vpd)	AM Peak Volume	PM Peak Volume	Queue Length (feet)	Average Delay (seconds)
Elm Street	5,000	175	295	125	35
Oliver Street	1,100	80	100	25	75
Short Street	4,800	220	240	100	34
Depot Street (Route 123)	19,700	1,085	885	475	48
Purchase Street	2,500	105	140	75	32
Prospect Street	2,200	90	120	75	32
Foundry Street (Route 106)	12,800	570	635	275	41

Source: MassDOT Highway Division supplemented by counts.
1 2030 Build Condition

- **Elm Street**. On Elm Street, a calculated queue length of 125 feet and average delay of 35 seconds are projected during the peak periods and could affect traffic operations at driveways near the crossing. Of particular concern is the driveway to the office/industrial building on the east side of the crossing. This driveway would be reconfigured.

- **Oliver Street**. On Oliver Street, a calculated queue length of 25 feet and average delay of 75 seconds during peak periods may affect driveways near the crossing. Of particular concern is the driveway to the office/industrial building on the northwest side of the crossing, which is adjacent to a play area. This driveway is within the railroad right-of-way; the driveway would be reconfigured and the play area (which is part of day care operation) would be relocated to safe location. The sidewalk would be extended through the crossing.

- **Short Street**. A calculated queue length of 100 feet and average delay of 34 seconds during peak periods on Short Street may affect the driveways immediately on either side of the crossing.

- **Depot Street (Route 123)**. On Depot Street (Route 123), a calculated queue length of 475 feet and average delays of 48 seconds during peak periods may affect the commercial and residential driveways immediately on either side of the crossing. The driveway immediately to the west of the crossing may need to be reconfigured.

- **Purchase Street**. A calculated queue length of 75 feet and average delay of 32 seconds at Purchase Street during the peak periods are considered to be minimal. However, the queue during peak periods may affect driveways and Granite Lane immediately adjacent to the crossing.

- **Prospect Street**. A calculated queue length of 75 feet and average delay of 32 seconds at Prospect Street during the peak periods are considered to be minimal. However, the queue may affect driveways immediately adjacent to the crossing.

- **Foundry Street**. On Foundry Street, the projected queue length of 275 feet and average delays of 41 seconds during peak periods may affect a residential driveway located 100 feet to the east.

- **Easton DPW driveway (private) and Gary Lane (private)**. On the Easton DPW driveway and Gary Lane (both private ways), the maximum queue lengths and average delays at the location are expected to be minimal. Gates and locks are being proposed for these locations. This location is not a public crossing.

Stoughton Grade Crossings (8) - Stoughton Alternatives—Eight public grade crossings are located in Stoughton and would be affected by the Stoughton and Whittenton Alternatives. Five of these grade crossings (Central Street, Simpson Street, School Street, Porter Street, and Wyman Street) are currently active rail crossings carrying commuter rail that would be modified to allow double-track operations. The addition of a second track and additional trains would result in negligible changes in traffic conditions or queue lengths at these crossings. A sixth crossing, at Brock Street crossing is considered active and has working signals but is rarely used today; therefore, for the purposes of this analysis, Brock Street is considered a reactivated crossing. Table 4.1-55 shows the traffic volumes and average delay at grade crossings in Stoughton that would be reactivated as part of the proposed project.

Table 4.1-55 Stoughton Grade Crossings—Traffic Volumes[1] and Average Delay Stoughton Alternatives

Crossing	Traffic Volume (vpd)	AM Peak Volume	PM Peak Volume	Queue Length (feet)	Average Delay (seconds)
Brock Street	3,260	440	810	750	105
Plain Street	8,000	370	510	225	39
Morton Street	1,700	125	180	100	33

Source: MassDOT Highway Division supplemented by counts.
1 2030 Build Condition

- **Brock Street**. On southbound Brock Street, a calculated queue length of 750 feet and average delay of 105 seconds are projected during the evening peak hour and would affect traffic operations at the intersection of Washington Street and Brock Street. Table 4.1-55 shows the traffic volume and average delay expected at the Brock Street grade crossing under the Build Condition.

- **Plain Street**. On Plain Street, the calculated queue length of 225 feet and average delay of 39 seconds may impact traffic operations at the intersection of Washington Street and Plain Street. These impacts are similar to those that may be realized at Brock Street, including impacts to driveways. Further study of the benefits of signalizing this intersection is also required and should be incorporated into a study with the Brock Street intersection.

- **Morton Street**. On Morton Street, a calculated queue length of 100 feet and an average delay of 33 sections would impact operations at the intersection of Washington Street and Morton Street. The grade crossing would be located approximately 25 feet west of this unsignalized intersection. When the crossing gates are down there would be insufficient storage distance for vehicles turning onto Morton Street from Washington Street. Private driveways immediately south of Morton Street would also experience the same difficulties. Additionally, the steep grade of Morton Street may pose a safety hazard in wet or snowy weather. To mitigate these concerns, Morton Street and the private driveways to the south would be closed and a bypass roadway constructed to the private grade separated crossing on Totham Farm Road. This concept would be further studied to evaluate the traffic impacts of these closures and the potential of rerouting traffic to Plain Street.

Canton Grade Crossings (3) - Stoughton Alternatives—Three crossings studied in Canton (Washington Street, Pine Street, and Will Drive) are located along the active commuter rail line. The construction of a second track along this section of the alignment and increased train activity would not result in substantial changes in traffic conditions or queue lengths at these crossings. As part of the proposed project, traffic signal preemption is recommended at the intersection of Washington Street and Revere Street to address queuing that may extend over the tracks during the peak hours.

Whittenton Alternatives Grade Crossing Impacts

Taunton Grade Crossings (12) – Whittenton Alternatives (12)—Twelve public grade crossings associated with the Whittenton Alternative are located in Taunton. This includes ten existing grade crossings along the existing, active Attleboro Secondary. The remaining two grade crossings consist of the reactivation of two inactive grade crossings at Whittenton Street and Warren Street. Table 4.1-56 shows the traffic volumes and average delay at these grade crossings. The Bay Street crossing is currently grade separated and is therefore not discussed in this section.

- **Whittenton Street**. A calculated queue length of 100 feet and average delays of 34 seconds are projected at Whittenton Street during peak periods, and may affect the commercial driveways on both sides of the crossing.

- **Warren Street**. Although traffic volume data was unavailable, Warren Street traffic volumes are anticipated to be low as a minor residential roadway. The maximum queue lengths and average delays are expected to be minimal at the Warren Street grade crossing location.

- **Danforth Street**. On Danforth Street, the maximum queue lengths and average delays are expected to be minimal and the projected queue of 125 feet would not impact any driveways or the Grosvenor Street or Perry Avenue intersections.

Table 4.1-56 Taunton Grade Crossings—Traffic Volumes[1] and Average Delay Whittenton Alternatives

Crossing	Traffic Volume (vpd)	AM Peak Volume	PM Peak Volume	Queue Length (feet)	Average Delay (seconds)
Whittenton Street	3,300	120	225	100	34
Warren Street	N/A	N/A	N/A	-	-
West Britannia St.	4,900	288	309	150	35
Danforth St.	4,045	213	272	125	35
Tremont St.	16,505	666	798	350	43
Oak St.	12,245	763	548	800	107
Porter St.	3,195	149	197	100	39
Cohannet St.	2,025	138	224	100	34
Winthrop St.	17,360	800	812	350	44
Harrison Ave.	2,025	163	124	75	33
Somerset Ave.	8,625	434	483	225	38
Weir St.	13,815	613	666	350	48

Source: MassDOT Highway Division supplemented by counts.
1 2030 Build Condition

- **Tremont Street**. The railroad corridor intersects Tremont Street at a skewed angle in a congested urban area with a number of business and residential driveways. This active grade crossing experiences similar (albeit infrequent) delays when freight trains service the various industrial uses in Taunton. The calculated queue length of 350 feet and average delays of 43 seconds are projected during peak periods, which may affect the driveways on both sides of the crossing and traffic operations at the adjacent Granite Street intersection. One driveway on the southbound approach would be reconfigured to access Tremont Street from the adjacent driveway curb cut.

- **Oak Street**. Located adjacent to the proposed Downtown Taunton Station and platform, the Oak Street crossing would have longer queues and delay due to the extended gate closure interval. A calculated 800 foot queue and 107 seconds of delay are projected during peak periods. The nearby traffic signal at the Oak Street and Tremont Street intersection has existing pre-emption for the tracks with an advance traffic signal mast arm located just west of the tracks to prevent queuing across the tracks. The South Coast Rail project would optimize the pre-emption settings for the Oak Street and Tremont Street intersection.

- **Porter Street**. With 39 seconds of delay and queue lengths of 100 feet or less, impacts are projected to be minimal at the Porter Street crossing. The projected queues may affect one or two residential driveways on either side of each crossing. Proposed grade crossing signal equipment locations will require the modification of one driveway. Guardrail is proposed along the railroad right-of-way to limit vehicular access from the abutting business.

- **Cohannet Street**. On Cohannet Street, the maximum queue lengths and average delays are expected to be minimal. However, the proposed grade crossing signal equipment locations would require reconfiguration of two driveways immediately on either side of the tracks and the closure of the driveway in the northwest quadrant.

- **Winthrop Street**. The Winthrop Street crossing is located between a small shopping center to the east and a residential area to the west. A calculated queue length of 350 feet and average delays of 44 seconds are projected during peak periods. Walnut Street, Harrison Street and driveways located within 350 feet of the tracks would be impacted by minor delays associated with the anticipated queues at the grade crossing. Supplemental advance railroad crossing signs are suggested for both Winthrop Street approaches due to sight distance restrictions to the east (horizontal alignment) and the west (vertical alignment).

- **Harrison Avenue**. On Harrison Avenue, the maximum queue lengths and average delays are expected to be minimal and the projected queue of 75 feet would only have minor impacts to a residential driveway and Walnut Street.

- **Somerset Avenue**. On Somerset Avenue, a calculated queue length of 225 feet and average delays of 38 seconds are projected during peak periods. East Walnut Street, Barnum Street and driveways located within 225 feet of the tracks may be impacted by minor delays associated with the anticipated queues at the grade crossing. The signalized intersection of Weir Street and Somerset Avenue is located approximately 430 feet to the north of the grade crossing. If the Whittenton Alternative is determined to be the LEDPA, intersection operations and queues should be evaluated to determine if signal pre-emption is required.

- **Weir Street**. On Weir Street, a calculated queue length of 350 feet and average delay of 48 seconds are projected during the peak periods and could affect traffic operations at driveways near the crossing and the intersections at White Street, Sumner Street and McSoley Avenue. Of particular concern is the proximity of the McSoley Street to the Weir Street crossing. McSoley Street intersects Weir Street within the active grade crossing area and therefore is proposed to be closed and traffic diverted to a new outlet to Weir Street. In addition, the driveway to the residence at the corner of Weir Street and White Street would be relocated from Weir Street to White Street. The driveway serving the property in the southeast quadrant would also be reconfigured.

Grade Crossing Incident Analysis

Table 4.1-57 summarizes the probability of an incident (regardless of the severity) occurring over the span of a year at each of the proposed at-grade crossings along the Stoughton Electric Alternative alignment as well as the probability of an incident occurring at each of the at-grade crossings that currently contain rail operations.

Table 4.1-57 Stoughton Electric Alternative Incident Predictor

Town/City	Street	Existing Probability. of an Incident/Year	Proposed Probability of an Incident/Year
Canton	Washington Street	7.9%	9.2%
	Pine Street	2.6%	2.9%
	Will Drive	2.2%	2.6%
Stoughton	Central Street	3.4%	4.1%
	Simpson Street	2.2%	2.6%
	School Street	2.7%	3.4%
	Porter Street	3.0%	3.5%
	Wyman Street	2.4%	2.9%
	Brock Street	2.4%	2.9%
	Plain Street	N/A	3.4%
Easton	Elm Street	N/A	4.0%
	Oliver Street	N/A	2.9%
	Gary Lane	N/A	3.6%
	Short Street	N/A	4.1%
	Depot Street	N/A	6.5%
	Purchase Street	N/A	3.6%
	Prospect Street	N/A	3.6%
	Foundry Street	N/A	6.0%
Raynham	Greyhound Park	N/A	0.4%
	Elm Street	N/A	4.0%
	Carver Street	N/A	5.7%
	Britton Street	N/A	3.3%
	King Phillip Street	N/A	4.0%
	East Britannia Street	N/A	4.4%
Taunton	Longmeadow Road	N/A	5.7%
	Dean Street – Route 44	1.3%	7.4%
	Ingell Street	8.9%	4.5%
	Pratt Street	0.8%	3.8%
Berkley	Cotley Street	0.3%	1.7%
	Padelford Street	0.5%	2.6%
	Myricks Street (Route 79)	0.6%	3.7%
Lakeville	Malbone Street	0.4%	2.4%
Freetown	Chace Road	0.4%	0.0%
	Braley Road	0.4%	4.0%
	East Chipaway Road	0.4%	3.8%
	Richmond Road - North	0.4%	4.0%
	Richmond Road - South	0.4%	4.0%
	Forge Road - South	0.4%	2.6%
	Elm Street	0.4%	2.8%
	High Street	0.3%	2.0%

Town/City	Street	Existing Probability. of an Incident/Year	Proposed Probability of an Incident/Year
	Copicut Road	0.2%	2.4%
	Brightman Lumber	0.1%	0.5%
New Bedford	Samuel Barnet Road	0.5%	2.9%
	Pig Farm Road	0.1%	4.0%
	Tarkiln Hill Road	0.5%	4.1%
	Nash Road	0.7%	4.0%

NA – Not Active

- *Canton* – Washington Street has the highest probability at 9.2 percent. This would be approximately one incident every 11 years.
- *Stoughton* – Central Street has the highest probability at 4.1 percent. This would be approximately one incident every 24 years.
- *Easton* – Depot Street has the highest probability at 6.5 percent. This would be approximately one incident every 15 years.
- *Raynham* – Carver Street has the highest probability at 5.7 percent. This would be approximately one incident every 18 years.
- *Taunton* – Dean Street (Route 44) has the highest probability at 7.4 percent. This would be approximately one incident every 14 years.
- *Berkley* – Myricks Street (Route 79) has the highest probability at 3.7 percent. This would be approximately one incident every 27 years.
- *Lakeville* – Malbone Street has the highest probability at 2.4 percent. This would be approximately one incident every 42 years.
- *Freetown* –Braley Road and Richmond Road have the highest probabilities at 4.0 percent. This would be approximately one incident every 25 years.
- *New* Bedford –Tarkiln Hill Road has the highest probability at 4.1 percent. This would be approximately one incident every 24 years.
- *Taunton* – West Britannia Street has the highest probability of future incidents at 4.1 percent. This would be approximately one incident every 25 years.

Table 4.1-58 summarizes the probability of an incident occurring over the span of a year at each of the proposed at-grade crossings along the Attleboro Secondary and Whittenton Branch portion of the Whittenton Electric Alternative alignment. This is the only portion of the Whittenton Alternatives alignment that differs from the Stoughton Alternatives. Incident probabilities along the shared portions of the alignment would be the same under the Whittenton Alternatives as listed in Table 4.1-57 for the Stoughton Alternatives.

Table 4.1-58 Whittenton Electric Incident Predictor, Attleboro Secondary and Whittenton Branch

Town/City	Street	Existing Probability of an Incident/Year	Proposed Probability of an Incident/Year
Taunton	Whittenton Street	0.0%	0.4%
	Warren Street	0.0%	0.4%
	West Britannia Street	0.7%	4.1%
	Danforth Street	0.7%	2.6%
	Tremont Street	1.0%	3.5%
	Oak Street	1.0%	3.5%
	Porter Street	0.7%	2.6%
	Cohannet Street	0.6%	2.6%
	Winthrop Street	1.0%	3.7%
	Harrison Avenue	0.6%	2.6%
	Somerset Avenue	0.8%	3.5%
	Weir Street	0.8%	3.5%

NA – Not Active

Along the Attleboro Secondary and Whittenton Branch portion of the Whittenton Alternatives, West Brittania Street would have the highest future incident probability at 4.1 percent. This would be equivalent to approximately one incident every 25 years. Danforth Street, Porter Street, Cohannet Street, and Harrison Avenue have the lowest future probability at 2.6 percent. This would be equivalent to approximately one incident every 39 years. The average probability that an incident would occur at any of the Whittenton Alternative at-grade crossings is 4.677 percent per year. By comparison, the Stoughton Alternative's Dean Street (Route 44) grade crossing along the portion of the Stoughton Line bypassed by the Whittenton Alternatives has the highest future incident probability at 7.4 percent, which would be equivalent to approximately one incident every 14 years. The average probability that an incident would occur at any of the Stoughton Alternative at-grade crossings is 4.944 percent per year.

Although both the Stoughton and Whittenton Alternatives have similar probabilities of an incident occurring at any one crossing, the probability of an incident along the Whittenton Alternative alignment in Taunton is double that of the Stoughton Alternative alignment because there are roughly double the number of grade crossings on the Whittenton alignment in Taunton.

According to MBTA data, the predicted frequency of an incident occurring throughout the MBTA's system and its 333 active at-grade crossings is 0.0199 in one year. The historical data from the past 10 years of an incident at any of the 333 active at-grade crossings in the MBTA's system has an observed probability of 0.009 in one year. Although the predicted frequency of an incident under the Stoughton Alternatives is 0.03618 in one year, the measures and precautions taken by the MBTA have made the probability less likely and provide a historical probability of 0.0009 in one year. With the MBTA continuing to take safety measures and precautions at all of their crossings on the South Coast Rail project, the predicted incident rate of 0.03618 is likely to be less.

Stations

Transportation analyses for the alternatives were conducted for all the planned station locations associated with the rail alternatives. The analysis of transportation impacts is based on projected ridership at each station. Since some stations are included in more than one alternative, each station

was analyzed only once using the highest ridership projection for the station from among the alternatives. This approach results in a worst case scenario analysis. As with the No-Build analysis, the Build analysis results are presented by community and station. For each of the stations analyzed (except for Taunton Station and Dana St. Station as explained below), vehicle trip generation was estimated based on these 2030 ridership forecasts.

To determine the potential impact the revised 2035 ridership results could have on the DEIS/DEIR traffic analyses and findings, 2035 ridership data were compared to the 2030 ridership data. Details of the comparison for the Stoughton and Whittenton Alternatives are shown in Appendix 3.2-H. In general, 2035 boardings are lower than the 2030 boardings, with a few exceptions. The Stoughton Electric 2035 ridership projects slightly higher inbound boardings during the morning peak period at three stations: Taunton, Fall River Depot, and Kings Highway. Breaking these increases down further to peak hour analysis of various travel modes, less than 26 additional vehicles are projected to drive and park at Fall River Depot and Kings Highway stations. Approximately 10 additional kiss and ride trips are projected for these two stations. Increases of peak hour trips at the Taunton Station are more significant, with Taunton Station projected to add 78 park and ride trips and 43 kiss and ride peak hour trips over the trip generation estimated in the DEIS/DEIR. While Fall River Depot and Kings Highway reflect minimal change in ridership, updated 2035 traffic analysis is provided for the Taunton Station.

In addition to Taunton Station, this section also presents traffic analysis for Dana Street Station, which was not included in the DEIS/DEIR station-level traffic impact analysis. It analyzes the transportation impacts of relocating the proposed Downtown Taunton Station, previously proposed as part of the Whittenton Alternative.

The 2030 DEIS/DEIR station boarding estimates were used to prepare traffic impact analyses for the relocated Stoughton Station.

The results of the Build analyses are presented for signalized and unsignalized intersections by community. The results include No-Build conditions LOS and highlight locations that operate at unacceptable levels of service during at least one peak hour. Intersections that degrade to unacceptable levels of service from No-Build conditions are denoted in **bold**. LOS analyses for all intersections are provided in Appendix 4.1-I.

New Bedford Transportation Impacts (All Rail Alternatives)

The two station locations proposed in New Bedford include:

- Whale's Tooth, which would be located east of Route 18 and north of Route 6
- King's Highway, which would be located south of King's Highway, east of the Route 140 interchange

The Whale's Tooth Station would be located between the intersections of Acushnet Avenue at Hillman Street and the intersection of Acushnet Avenue at Pearl Street. Access to the proposed station would be via an unsignalized driveway on Acushnet Avenue. An existing bus stop is located immediately adjacent to the proposed station. Logan Street and Hillman Street provide pedestrian and bicycle connections to the station from the neighborhood west of Route 18.

The King's Highway Station is located behind the existing retail mall in the Shaw's Shopping Center. Access to the proposed station would be provided via the signalized Shaw's Shopping Center driveway. Pedestrian access would be provided via a pedestrian walkway across from Tarkiln Hill Road. Bicycle access would be provided via King's Highway and the proposed station driveway.

Traffic Operations—Design year (2030) Build condition traffic volumes for the study area roadways were determined by estimating site-generated traffic volumes and distributing these volumes over study area roadways within New Bedford. These site generated volumes were added to the No-Build traffic volumes to create the 2030 Build condition traffic volume networks, which are depicted in Figures 4.1-54 through 4.1-57.

The projected number of vehicle trips in and out of the Whale's Tooth and King's Highway stations during the morning and evening peak hours are shown in Table 4.1-59. The trip generation for the New Bedford stations is based on ridership projections for the Attleboro Alternative.

Table 4.1-59 Park-and-Ride and Vehicular Drop-Off Vehicle Trips:[1] New Bedford Stations

		Morning Peak Hour		Evening Peak Hour	
Station	**Type of Trip**	**In**	**Out**	**In**	**Out**
Whale's Tooth	Park-and-Ride	146	16	10	120
	Drop-off	44	44	35	35
	Total Vehicles	190	60	45	155
King's Highway	Park-and-Ride	143	16	8	114
	Drop-off	28	28	21	21
	Total Vehicles	171	44	29	135

1 The number of park-and-ride vehicle trips is calculated by dividing the number of park-and-ride riders by a 1.05 vehicle occupancy rate (VOR). The number of vehicular drop-off vehicle trips assumes one rider per vehicle.

The directional distribution of station-generated traffic is a function of population distribution, vehicle-owning households, existing travel patterns on area roadways, and traffic conditions. The trip distribution for the park-and-ride trips associated with New Bedford stations is based on ridership data provided by CTPS, which take into account these factors. Table 4.1-60 provides the geographic distribution of these trips.

Table 4.1-60 New Bedford Trip Distribution

To/From	King's Highway Station	Whale's Tooth Station
North	8%	21%
South	27%	17%
East	23%	30%
West	43%	32%

Source: CTPS Travel Demand Model.

The park-and-ride traffic was distributed to the study area roadways based on these percentages. Drop-off traffic was added separately and is based on existing travel patterns on area roadways near the proposed station locations.

The intersection levels of service based on the addition of rail related traffic are shown in Table 4.1-61. At most of the signalized or unsignalized intersections analyzed, no traffic operating deficiencies would

be created by the Whale's Tooth Station. Four unsignalized locations would continue to operate at a deficient LOS E and LOS F during one or both peak hours. These include Coggeshall Street at North Front Street during both peak hours and Coggeshall Street at Purchase Street, Purchase Street at Weld Street and Purchase Street at Route 18 SB ramp during the evening peak hour. The station driveway would operate at LOS B during both peak hours.

There would be no changes from acceptable LOS at the intersections analyzed for the King's Highway station. The unsignalized intersections of Mount Pleasant Street and Route 140 SB Ramps would continue to operate at LOS F during the morning peak hour as it does under No-Build conditions. The intersection of King's Highway at Mount Pleasant Street and the unsignalized intersections of Church Street at Park Avenue, Mount Pleasant Street and Route 140 SB Ramps and King's Highway at Tarkiln Hill Road would continue to operate at LOS E or F during the evening peak hour as they do under No-Build conditions.

Traffic Signal Warrants—Six intersections were evaluated against the traffic signal warrant for the peak hour period:

- Coggeshall Street at North Front Street
- Coggeshall Street at Purchase Street
- Purchase Street at Weld Street and Route 18 southbound ramp
- Purchase Street at Route 18 southbound ramp
- Mount Pleasant Street at Route 140 southbound ramps
- Acushnet Avenue at Station Driveway

The intersection of Coggeshall Street at North Front Street meets the requirements set forth by the MUTCD for traffic signal installation based on future peak hour traffic volumes.

The Coggeshall Street at Purchase Street intersection potentially meets the crash experience warrant by having more than five correctable crashes in a recent one-year period. A full eight-hour warrant analysis will be required to confirm this warrant. This analysis would be completed during the preliminary engineering phase of the project. The Mount Pleasant Street at Route 140 southbound ramps intersection is projected to meet peak hour traffic signal warrants with or without the South Coast Rail project. Project traffic through this intersection constitutes only a minor 2 percent increase in traffic from No-Build conditions.

The Purchase Street at Weld Street and Route 18 southbound ramp, Purchase Street at Route 18 southbound ramp and the Acushnet Avenue at Station Driveway intersections do not meet peak hour traffic signal warrants based on the projected future traffic volumes.

NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Pedestrians and Bicycles—The travel demand and ridership estimates completed by CTPS indicate that about 150 pedestrian/bicycle trips would access the Whale's Tooth Station on a daily basis; which would increase pedestrian and bicycle activity in the vicinity of Acushnet Avenue. At King's Highway Station, approximately 120 pedestrian/bicycle trips could be expected. The majority of the infrastructure needed to support non-motorized transportation at both proposed station exists currently and would not be adversely impacted by the change in number of pedestrians or bicyclists on study area roadways.

Traffic signal timing and phasing changes would be required at the intersection of Mill Street at Pleasant Street to accommodate pedestrian demands. These changes are discussed further in Section 4.1.5, Mitigation Measures. Pedestrian demands associated with the proposed Whale's Tooth Station would also require a new sidewalk on Acushnet Avenue between Hillman Street and the proposed station driveway and a crosswalk across Acushnet Avenue at Hillman Street.

To accommodate increased pedestrian demand at King's Highway Station, changes to the pedestrian signal phases at the intersections of Church Street/Tarkiln Hill Road and Jones Street/Mount Pleasant Street would be required. These changes are discussed further in Section 4.1.5, Mitigation Measures.

Neither of the proposed New Bedford Station locations would physically alter designated bicycle facilities nor disrupt future plans for either on-road or off-road facilities in the study area. To accommodate demand, bicycle parking and storage locations would be maximized using available space.

Parking—The Whale's Tooth station is proposed to have 694 parking spaces (15 of these handicapped accessible) to serve as a shared use parking facility with existing ferry service. The proposed project would not physically alter the existing public parking supply or impact parking availability within New Bedford. Based on the projected daily park-and-ride ridership, the parking supply would be sufficient to meet the peak parking demand for 310 spaces. The surplus of 384 spaces would remain available for ferry passenger use.

The King's Highway station is proposed to have 360 spaces (12 of these handicapped accessible) to serve as a shared use parking facility with the existing cinema. Since peak parking demand for the cinema would occur during the evening, after most commuters have returned home, the available parking supply should be adequate to meet the commuter rail peak demand for 300 spaces.

Freetown Transportation Impacts

The Freetown station site would be located east of South Main Street south of Route 24 Exit 9 between the Stop & Shop Distribution Center and the planned entrance to the Riverfront Business Park (on the opposite side of the roadway). Access to the proposed station would be via an unsignalized driveway and adjacent sidewalk, thus providing access for all users.

Traffic Operations—As discussed above, design year (2030) Build condition traffic volumes for the study area roadways were determined by estimating site-generated traffic volumes and distributing these volumes over study area roadways within Freetown. These site generated volumes were added to the No-Build traffic volumes to create the 2030 Build condition traffic volume networks, which are depicted in Figures 4.1-58 and 4.1-59.

The projected number of vehicle trips in and out of the Freetown station during the morning and evening peak hours are shown in Table 4.1-62. The trip generation for this station is based on the projected ridership with the Stoughton Alternative.

Table 4.1-62 Park-and-Ride and Vehicular Drop-Off Vehicle Trips:[1] Freetown Station

		Morning Peak Hour		Evening Peak Hour	
Station	**Type of Trip**	**In**	**Out**	**In**	**Out**
Freetown	Park-and-Ride	81	9	5	45
	Drop-off	17	17	9	9
	Total Vehicles	98	26	14	54

1 The number of park-and-ride vehicle trips is calculated by dividing the number of park-and-ride riders by a 1.05 vehicle occupancy rate (VOR). The number of vehicular drop-off vehicle trips assumes one rider per vehicle.

The trip distribution for the park-and-ride trips associated with the Freetown Station is based on ridership data provided by CTPS, which take into account factors such as population, existing travel patterns, and traffic congestion, as noted above. Table 4.1-63 provides the geographic distribution of these trips.

Table 4.1-63 Freetown Trip Distribution

To/From	Distribution
North	54%
South	41%
East	5%
West	0%

Source: CTPS Travel Demand Model.

The park-and-ride traffic was distributed to the study area roadways based on these percentages. Drop-off traffic was added separately and is based on existing travel patterns on area roadways near the proposed station locations.

The intersection levels of service based on the addition of rail related traffic are shown in Table 4.1-64. Seven signalized intersections were analyzed under No-Build and Build conditions. All but one location would operate at acceptable levels of service under both conditions. The intersection of South Main Street at the Route 24 northbound ramps would continue to operate at LOS E during the evening peak

hour. No additional unsignalized intersections would become deficient during either the morning or evening peak hour.

Table 4.1-64 Freetown Intersection Capacity Analysis—2030 Build Conditions vs. No-Build Conditions All Alternatives

L = Left-turn; T = Through; R = Right-turn; All=all movements
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound Traffic Signal Warrants

Traffic Signal Warrants—Four intersections were evaluated against the traffic signal warrant for the peak hour period:

- South Main Street at High Street
- South Main Street at Ridge Hill Road
- South Main Street at Narrows Road
- South Main Street at Freetown Station Driveway

The South Main Street and Ridge Hill Road intersection is projected to meet peak hour traffic signal warrant during the evening peak hour with or without the South Coast Rail project. Project traffic

through this intersection would constitute only a minor 1.5 percent increase in traffic from No-Build conditions.

The other unsignalized intersections along South Main Street do not meet peak hour traffic signal warrants based on the projected future traffic volumes.

Pedestrians and Bicycles—The travel demand and ridership estimates completed by CTPS indicate that about 40 pedestrian/bicycle trips would access Freetown Station on a daily basis which would increase pedestrian and bicycle activity along South Main Street. The majority of the infrastructure needed to support pedestrian and bicycle traffic to the proposed station exists currently and would not be adversely impacted by the change in number of pedestrians or bicycles on study area roadways.

To accommodate pedestrian demands, the existing sidewalk along the east side of South Main Street would be extended south (about 1,600 feet) to the station driveway.

The proposed station location would not physically alter designated bicycle facilities or disrupt future plans for either on road or off-road facilities in the study area. To accommodate demand, bicycle parking and storage locations would be maximized using available space.

Parking—Freetown Station is proposed to have 174 parking spaces (of which seven would be handicapped accessible). An additional eight parking spaces would be reserved for drop-off activity. The proposed project would not physically alter the existing public parking supply or impact parking availability within Freetown. Based on the projected daily park-and-ride ridership, the parking supply would be sufficient to meet the peak parking demand for 170 spaces.

Fall River Transportation Impacts (All Rail Alternatives)

Fall River has two proposed station locations that would serve both the Stoughton and Whittenton Alternatives:

- Fall River Depot, which would be located 1 mile north of downtown Fall River on North Davol Street between Pearce Street and Turner Street.
- Battleship Cove, which would be located on Ponta Delgada Boulevard west of Route 138 and south of I-195 and the Fall River Heritage State Park.

Access to the proposed Fall River Depot Station would be via an unsignalized driveway located on North Davol Street. A separate entrance and exit driveway are provided for drop-off traffic and connecting local bus service. Pearce Street and Turner Street provide pedestrian and bicycle connections to the station from the neighborhood east of the railroad tracks.

At Battleship Cove, access to the proposed station would be provided via a drop-off loop on Ponta Delgada Boulevard. No parking is proposed for this station. Pedestrian and bicycle access would also be provided via Water Street and Ponta Delgada Boulevard.

Traffic Operations—As discussed above, design year (2030) Build condition traffic volumes for the study area roadways were determined by estimating site-generated traffic volumes and distributing these volumes over study area roadways within Fall River. These site generated volumes were added to the

No-Build traffic volumes to create the 2030 Build condition traffic volume networks, which are depicted in Figures 4.1-60 and 4.1-61.

The projected number of vehicle trips in and out of the Fall River Depot and Battleship Cove stations in the morning and evening peak hours are shown in Table 4.1-65. The trip generation of the Fall River stations is based on projected ridership for the Attleboro Alternative.

Table 4.1-65 Park-and-Ride and Vehicular Drop-Off Vehicle Trips:[1] Fall River Stations All Alternatives

Station	Type of Trip	Morning Peak Hour In	Morning Peak Hour Out	Evening Peak Hour In	Evening Peak Hour Out
Fall River Depot	Park-and-Ride	184	25	14	166
	Drop-off	26	26	22	22
	Total Vehicles	210	51	36	188
Battleship Cove	Park-and-Ride	0	0	0	0
	Drop-off	34	34	25	25
	Total Vehicles	34	34	25	25

1 The number of park-and-ride vehicle trips is calculated by dividing the number of park-and-ride riders by a 1.05 vehicle occupancy rate (VOR). The number of drop-off vehicle trips assumes one rider per vehicle.

The directional distribution of station-generated traffic is a function of population distribution, vehicle-owning households, existing travel patterns on area roadways, and traffic conditions. The trip distribution for the park-and-ride trips associated with Fall River Depot Station is based on ridership data provided by CTPS, which take into account these factors. Table 4.1-66 provides the geographic distribution of these trips.

Table 4.1-66 Fall River Trip Distribution

To/From	Distribution
North	20%
South	58%
East	22%
West	0%

Source: CTPS Travel Demand Model.

The park-and-ride traffic was distributed to the study area roadways based on these percentages. Drop-off traffic was added separately and is based on existing travel patterns on area roadways near the proposed station locations. Only drop-off traffic was generated by Battleship Cove Station, as no long-term parking is planned.

The intersection levels of service based on the addition of rail related traffic are shown in Table 4.1-67. Three signalized and five unsignalized intersections, including the station driveway, were analyzed for the Fall River Depot station under Build conditions. All intersections would operate at acceptable levels of service.

1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
4 average control delay for the critical movement, rounded to the nearest whole second, for unsignalized intersections
L = Left-turn; T = Through; R = Right-turn; All = All movements
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

The Battleship Cove station is not anticipated to serve a substantial amount of regular commuter rail ridership but is intended to provide tourist access to the attractions at Battleship Cove. There would be limited space available to accommodate drop-off and pick-up activity. No substantial change in LOS would occur at the four unsignalized intersections that were analyzed. The proposed station driveway would operate at LOS B during both peak hours.

Traffic Signal Warrants—Three intersections were evaluated against the traffic signal warrant for the available peak hour periods:

- Anawan Street at Davol Street
- Central Street at Davol Street
- North Davol Street at Station Driveway

The Anawan Street at Davol Street intersection is projected to meet peak hour traffic signal warrants with or without the South Coast Rail project. Project traffic through this intersection constitutes only a minor 3 percent increase in traffic from No-Build conditions.

The Central Street at Davol Street and the North Davol Street at Station Driveway intersections do not meet peak hour traffic signal warrants based on the projected future traffic volumes.

Pedestrians and Bicycles—The travel demand and ridership estimates completed by CTPS indicate that about 280 non-motorized person trips (pedestrians and bicycles) would access Fall River Depot Station on a daily basis which would increase pedestrian and bicycle activity in the vicinity of President Avenue, Davol Street, and North Main Street. At Battleship Cove Station, approximately 180 pedestrian/bicycle trips would be expected. The majority of the pedestrian and bicycle infrastructure needed to support both proposed stations exists currently and would not be adversely impacted by the change in number of pedestrians or bicyclists on study area roadways.

Traffic signal timing and phasing changes would be required at the intersections of Davol Street Northbound/President Avenue and North Main Street/President Avenue to accommodate pedestrian demands at Fall River Depot Station. These changes are discussed further Section 4.1.5, Mitigation Measures.

To accommodate increased pedestrian demand at Battleship Cove Station, crosswalks across Broadway and Central Street would be restriped. Sidewalks and crosswalks elsewhere in the vicinity of Battleship Cove are adequate to handle the expected demand.

Neither of the proposed station locations would physically alter designated bicycle facilities nor disrupt future plans for either on-road or off-road facilities in the study area. To accommodate demand, bicycle parking and storage locations would be maximized using available space.

Parking—The Fall River Depot station is proposed to have 513 parking spaces (of which 11 would be handicapped accessible). An additional 10 parking spaces would be reserved for drop-off activity. The proposed project would not physically alter the existing public parking supply or impact parking availability within Fall River. Based on the projected daily park-and-ride ridership, the parking supply would be sufficient to meet the peak parking demand for 430 spaces. No short or long-term parking would be provided at Battleship Cove.

Taunton Transportation Impacts

Traffic operations were analyzed for three station locations in the City of Taunton:

- Taunton Depot (all alternatives), which would be accessible from Route 140 west of the Route 24 interchange
- Dana Street (Whittenton Alternatives)
- Taunton (Stoughton Alternative), which would be located on Arlington Street just north of Dean Street (Route 44)

The Taunton Depot Station (associated with both rail alternatives) would be located behind the existing retail mall at Taunton Depot Drive. Access to the proposed station would be provided via the signalized intersection of Route 140 and Taunton Depot Drive. Pedestrian access would be provided via a

pedestrian walkway along Route 140 and pedestrian crossing controls at Taunton Depot Drive. Bicycle access would be provided via Route 140 and Taunton Depot Drive.

Access to the proposed Dana Street Station (associated with the Whittenton Alternative) would be via unsignalized intersections Dana Street. Pedestrian walkways would be provided that lead to the platform. Additional sidewalks would be constructed along Dana Street and Danforth Street.

At Taunton Station (Dean Street) (associated with the Stoughton Alternative), access to the proposed station would be provided via an unsignalized intersection on Arlington Street. Major access to the station would be provided from the signalized intersection of Arlington Street with Dean Street. Pedestrian access would be provided via pedestrian sidewalks along Dean Street and Arlington Street. Bicycle access would be provided via Arlington Street and Dean Street.

Traffic Operations- Taunton Depot Station—Design year (2030) Build condition traffic volumes for the study area roadways were determined by estimating site-generated traffic volumes and distributing these volumes over study area roadways within Taunton. These site generated volumes were added to the No-Build traffic volumes to create the 2030 Build condition traffic volume networks, which are depicted in Figures 4.1-62 and 4.1-63.

The projected number of vehicle trips in and out of the Taunton Depot station in the morning and evening peak hours are shown in Table 4.1-68. The trip generation is based on the DEIS/DEIR projected ridership for the Stoughton Alternative.

Table 4.1-68 Park-and-Ride and Vehicular Drop-Off Vehicle Trips:[1] Taunton Depot Station

Station	Type of Trip	Morning Peak Hour In	Morning Peak Hour Out	Evening Peak Hour In	Evening Peak Hour Out
Taunton Depot (all alternatives)	Park-and-Ride	160	20	12	128
	Drop-Off	18	18	14	14
	Total Vehicles	178	38	36	144

1 The number of park-and-ride vehicle trips is calculated by dividing the number of park-and-ride riders by a 1.05 vehicle occupancy rate (VOR). The number of vehicular drop-off vehicle trips assumes one rider per vehicle.

The intersection levels of service based on the addition of rail-related traffic are shown in Table 4.1-69. There would be no change in LOS under Build conditions at six of the seven signalized intersections analyzed for the Taunton Depot station location. The intersection of Route 140 at Hart Street during the morning and evening peak hours would continue operating at a deficient LOS, declining from LOS E to LOS F. No unsignalized intersections were analyzed for the Taunton Depot Station.

Traffic Operations- Dana Street Station—Dana Street Station is approximately 0.5 mile north of the previously-proposed Downtown Taunton Station and would be served by many of the same roadways that provided access to the Downtown Taunton Station. In addition to the station site relocation, revised ridership projections have been developed, which further change traffic operations. The ridership results show a decrease in proposed auto demand to the station.

Future 2030 ridership projections were developed by the Central Transportation Planning Staff (CTPS) for the previously proposed Downtown Taunton Station. These projections have since been revised to represent a 2035 condition at the proposed Dana Street Station. Table 4.1-70 summarizes the previous and current ridership projections for the two conditions under the Whittenton Alternative. As shown, ridership to the Dana Street station is projected to be between 48 and 63 percent less than was projected for the Downtown Taunton Station.

Table 4.1-70 Downtown Taunton/Dana Street Station Ridership Projection Comparison

Boardings	2030 Downtown Taunton Condition	2035 Dana Street Condition	Difference	Percent Difference
Daily	850	310	-540	-64%
AM Peak	460	240	-220	-48%

Source: CTPS

The reduction in ridership results in reduced vehicle trips to Dana Street station when compared to the Downtown Taunton Station. The reduction in vehicle trips is shown in Table 4.1-71. The DEIS/DEIR presented a full analysis of the Downtown Taunton Station for both the morning and evening peak hours using ridership boarding and alighting information provided by CTPS. Only morning boarding information was provided as part of the current ridership estimates, therefore for the purposes of this analysis it is assumed peak hour trips are the same magnitude (reversed direction) during the morning and evening peak hours.

Total	314	155	-159

Source: CTPS
vph vehicles per hour
1 PM data not provided by CTPS; assumed to be reverse impact of AM peak hour.

The vehicle trips related to the proposed Dana Street Station are less than half of the previous estimates; directly attributable to an overall reduction in ridership projected by CTPS. This removes a substantial amount of project-related vehicular traffic from the downtown Taunton area and reduces project impacts related to the station. Although it is projected by CTPS that a higher percentage of riders would drive to a station on Dana Street (69 percent of riders) when compared to Downtown Taunton (44 percent of riders drive), the overall vehicle trips are still substantially lower.

To assess the effects of these changes, a level of service analysis was revised for the intersection of Route 140/Taunton Street at Oak Street, which is the highest-volume intersection in the study area previously defined for the Downtown Taunton Station. As traffic accessing the new Dana Street Station would also likely use this critical intersection, a revised analysis was prepared to assess new impact. Table 4.1-72 presents a comparison of the traffic operations using 2030 Whittenton ridership estimates for Downtown Taunton and 2035 Whittenton ridership estimates for Dana Street.

1 Defacto left-turn during weekday evening peak hour

Given the substantial reduction in ridership between the Downtown Taunton Station and the currently proposed Dana Street Station, traffic operations at the intersection of Route 140/Tremont Street at Oak Street are projected to be improved when compared to the previous analysis. Several intersection movements are still projected to operate at a poor LOS E or LOS F during the 2035 evening peak hour. Although traffic impacts are lower, the mitigation committed to in the DEIS/DEIR would still be recommended because of the proximity of the intersection to the adjacent grade crossing. These measures are described in the mitigation section below.

Traffic Operations-Taunton Station—Table 4.1-73 summarizes the previous (2030) and current (2035) ridership projections for Taunton Station under the Stoughton Electric Alternative. As shown, 2035 ridership estimates at Taunton Station are 72 and 118 percent higher, for total daily and AM peak ridership, respectively, than previous 2030 estimates.

Table 4.1-73 Taunton Station Ridership Projection Comparison

Boardings	2030 Taunton Station	2035 Taunton Station	Difference	Percent Difference
Daily	360	620	260	72%
AM Peak	220	480	260	118%

Source: CTPS

The increase in ridership translates to a corresponding increase in vehicle trips to Taunton Station when compared to the DEIS/DEIR analysis. The revised vehicle trip projections are provided in Table 4.1-74. The DEIS/DEIR presented a full analysis for both the morning and evening peak hours using ridership boarding and alighting information provided by CTPS. Only morning boarding information was provided as part of the December 2012 ridership estimates, therefore for the purposes of this analysis it is assumed peak hour trips are the same magnitude (reversed direction) during the morning and evening peak hours.

Table 4.1-74 Taunton Station Vehicle Trip Comparison

Trips (vph)	2030 Taunton Station	2035 Taunton Station	Difference
AM Peak Hour

Exit	36	119	83
Total	59	177	118

Source: CTPS
vph vehicles per hour
1 PM data not provided by CTPS; assumed to be reverse impact of AM peak hour.

The vehicle trips related to the projected changes in ridership are higher than previous 2030 estimates. This is attributed to an overall increase in ridership projected by CPTS and a projected increase in the percentage of riders who would drive to a station (56 percent of riders) when compared to the DEIS/DEIR analysis (38 percent of riders drive).

To assess the effects of these changes, the DEIS/DEIR level of service analysis was revised for all intersections in the Taunton Station study area. Table 4.1-75 presents a comparison of the 2030 No-Build and 2035 Build traffic operations under the Stoughton Electric Alternative.

1 volume-to-capacity ratio
2 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
3 level of service
4 average control delay for the critical movement, rounded to the nearest whole second, for unsignalized intersections
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound; NA = Not Applicable

The overall results of the level of service analysis are generally the same as presented in the DEIS/DEIR. Mitigation measures are required to offset project related impacts and are described in the mitigation section below. One location, Arlington Street at School Street (where mitigation was not previously recommended), shows project-related impacts that affect level of service such that mitigation is now required.

When compared to the DEIS/DEIR delay and level of service results, the intersection of Dean Street at Longmeadow Street realizes a small increase in delay (10 additional seconds during the morning peak hour and five additional seconds during the evening peak hour).

Traffic Signal Warrants—Two intersections were evaluated against the traffic signal warrant for the peak hour period:

- Washington Street at Frederick Martin Parkway
- Arlington Street at Taunton Station Driveway

The intersection of Washington Street at Frederick Martin Parkway meets the requirements set forth by the MUTCD for traffic signal installation based on future peak hour traffic volumes.

The Arlington Street at Taunton Station Driveway intersection does not meet peak hour traffic signal warrants based on the projected future traffic volumes.

Pedestrians and Bicycles—The travel demand and ridership estimates completed by CTPS indicate that about 80 trips would access Taunton Depot Station (all alternatives) on foot or by bicycle on a daily basis, which would increase pedestrian and bicycle activity in the vicinity of Route 140 and Hart Street. At Dana Street Station (Whittenton Alternatives), approximately 50 pedestrian/bicycle trips would be expected and at Taunton Station about 230 pedestrian/bike trips would be expected. Increased pedestrian and bicycle demands at either of these stations would be realized in the vicinity of Downtown Taunton, particularly along Route 44, Route 138, Oak Street and/or Arlington Street. The majority of the infrastructure needed to support pedestrian and bicycle access to the proposed stations exists currently and would not be adversely impacted by the change in number of pedestrians on study area roadways.

To accommodate pedestrian demand related to Taunton Depot Station, a sidewalk would be required within the Target shopping center. The sidewalk is necessary to delineate the pedestrian right-of-way from Route 140 to the station platform. To accommodate pedestrian demand related to Taunton Station (Stoughton Alternative) traffic signal timing and phasing changes would be required at the intersection of Dean Street and Longmeadow Street. A high visibility crosswalk with a passive flashing pedestrian crossing sign would also be needed. Finally, to support Downtown Taunton pedestrian demands, a number of traffic signal timing adjustments would be needed. These adjustments would occur at the intersections of:

- Weir Street at Broadway
- Washington Street at Court Street
- Washington Street at Fredrick Martin Boulevard
- Washington Street at Tremont Street

These mitigation measures are discussed further below in Section 4.1.5, *Mitigation Measures*.

Neither of the proposed station locations would physically alter designated bicycle facilities nor disrupt future plans for either on-road or off-road facilities in the study area. To accommodate demand, bicycle parking and storage locations would be maximized using available space.

Parking—The Taunton Depot Station (both rail alternatives) is proposed to have 442 parking spaces (eight of these handicapped accessible). An additional 14 parking spaces would be reserved for drop-off activity.

Dana Street Station (Whittenton Alternatives) would have 477 spaces (9 of which are handicapped accessible).

Two hundred and nine (209) spaces are proposed at Taunton Station (Stoughton Alternative), including seven that are handicapped accessible. The Build Alternatives would not physically alter the existing public parking supply or impact parking availability within Taunton. Based on the projected daily park-and-ride ridership, the parking supply at each station would be sufficient to meet the peak parking demand for 320, 590, 120 spaces, respectively.

Relocated Stoughton Station Transportation Impacts

Under the Stoughton and Whittenton Alternatives, the existing railroad tracks for the Stoughton Station will be realigned and the station platform will be relocated south to the site bounded to the north by Wyman Street, west by Morton Street, and south by Brock Street. The relocated station will have two driveways: a north driveway off of Morton Street, and a south driveway off of Brock Street. As part of the station relocation, parking will be consolidated to one parking lot and increased up to 701 parking spaces, which includes 6 kiss-and-ride spaces and 17 handicap spaces.

The following sections present the transportation analysis associated with the relocation of Stoughton Station and the increase in available parking. In general, traffic conditions would improve as a result of relocating the Stoughton Station.

Station Trip Generation and Redistribution—All station-related vehicle trips were redistributed to the new driveways and throughout the roadway network for the Build Condition analysis. New vehicle trips, generated by either the expanded service or increase in available parking, were then added to the redistributed traffic volume network to create the Build Condition traffic volume networks depicted in Figures 4.1-64 and 4.1-65. Table 4.1-76 presents the projected number of new vehicle trips expected under the Build Condition.

Table 4.1-76 Relocated Stoughton Station Projected New Vehicle Trips

	Morning Peak Hour		Evening Peak Hour	
Type of Trip	In	Out	In	Out
Park-and-Ride	46	11	12	52
Kiss-and-Ride	-10	1	0	-5

As shown in Table 4.1-76, the number of kiss-and-ride trips would decrease relative to the No-Build condition. This can be attributed to a shift in the mode of access by riders. With the expansion of service, some riders currently boarding in Stoughton would board farther south, eliminating the need to be dropped off at the station. Other riders who are currently dropped off would shift to park-and-ride, as the available parking will increase under the Build Condition.

Traffic Operations Analysis—The Build Condition traffic operation analyses are shown in Table 4.1-77 through Table 4.1-79.

Table 4.1-77 Relocated Stoughton Station Signalized Intersection Capacity Analysis

		No-Build Condition			Build Condition		
Location	**Period**	**v/c [1]**	**Delay [2]**	**LOS [3]**	**v/c [1]**	**Delay [2]**	**LOS [3]**
Porter Street at Washington Street(Route 138)	Weekday Morning	0.73	22	C	0.68	20	C
	Weekday Evening	0.94	60	E	0.88	53	D
Pleasant Street at Park Street (Route 27)	Weekday Morning	0.96	45	D	0.92	36	D
Washington Street (Route 138)	Weekday Evening	0.83	27	C	0.78	24	C

Source: Synchro 7 (Build 773, Rev 8) software
1 volume-to-capacity ratio
2 average delay in seconds per vehicle
3 level of service

As discussed above, relocating Stoughton Station parking would redistribute station related traffic through study area intersections. A portion of traffic would access the parking lot driveway at Brock Street and no longer travel through Stoughton Center. As a result, the delay for the signalized intersections would improve slightly. The level of service at the intersection of Porter Street at Washington Street would improve from LOS E to LOS D. Complete traffic operations analysis results are provided in Appendix 4.1-K.

Relocating Stoughton Station would also eliminate the existing MBTA Lot Driveway on Wyman Street and substantially reduce or eliminate traffic at the Trackside Plaza South Driveway, eliminating most vehicle conflicts at this location. Level of service results for this intersection are not provided in Tables 4.1-78 and 4.1-79 since no delay would occur. Field observations indicate that traffic is currently using the Trackside Plaza South Driveway to access the station, while patrons of Trackside Plaza businesses use other driveways on Summer Street and Canton Street.

At the intersection of Brock Street at Washington Street, the demand for the eastbound Brock Street and westbound Kinsley Street approaches would increase substantially. The eastbound Brock Street approach and westbound Kinsley Street approach would deteriorate from LOS E to LOS F and LOS D to LOS F, respectively, during the morning peak hour. During the evening peak hour, the eastbound and westbound approach would continue to operate deficiently at LOS F.

Queue Analysis- A queue analysis was conducted to compare the queues at signalized study area intersections under the No-Build Condition and the Build Condition. Table 4.1-80 presents the results of the analysis; complete results are provided in Appendix 4.1-K.

Table 4.1-80 Relocated Stoughton Station Vehicle Queue Analysis

	SW RT	340	0	0	0	0

Source: Synchro 7 (Build 773, Rev 8) software
Note:
1 95th percentile queue length in feet
# 95th percentile volume exceeds capacity; queue may be longer.
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound; LT = left-turn; RT = right-turn

When compared to the No-Build Condition, queue lengths for the Build Condition would be noticeably shorter at the intersection of Porter Street at Washington Street: for the eastbound Porter Street right-turn lane during the evening peak hour and for the northbound Washington Street left-turn lane during both morning and evening peak hours.

At the intersection of Pleasant Street at Park Street/Washington Street, northbound Park Street queue lengths would be noticeably shorter during the morning and evening peak hours. The reduction in queue lengths is attributed to the redistribution in traffic on study area roadways that would result from relocating the Stoughton Station.

Pedestrians and Bicycles-The travel demand and ridership estimates completed by CTPS indicate that approximately 220 additional pedestrians/bicycle trips would be expected daily under the Build Condition. With the relocation of Stoughton Station, pedestrians will likely access the station via Morton Street, Brock Street and Washington Street. Currently, sidewalks are provided on the east side of Morton Street, north side of Brock Street and along both sides of Washington Street. The majority of the infrastructure needed to support pedestrian and bicycle access to the proposed station exists currently and would not be adversely impacted by the change in the number of pedestrians within the study area.

Signal Warrant Analysis- A signal warrant analysis was conducted to determine whether a traffic signal should be installed at the intersection of Washington Street at Brock Street. This intersection is expected

to see a substantial increase in traffic volume due to relocating the Stoughton Station. The analysis showed that a signal is warranted at this intersection due to traffic volume.

Easton Transportation Impacts (Stoughton and Whittenton Alternatives)

There are two stations planned in Easton:

- North Easton, which would be located on the Stoughton town line off Roche Bros Way
- Easton Village, which would be located off Sullivan Street just south of Oliver Street

Access to the proposed North Easton Station would be via the existing signalized Roche Brothers Shopping Center driveway located on Route 138 just south of the Stoughton town line. This driveway would serve vehicular and bicycle users. A sidewalk would be constructed along the access road to provide access for pedestrians.

At Easton Village, access to the proposed station would be provided via a drop-off loop on Sullivan Street. No parking is proposed for this station. Pedestrian and bicycle access would be provided via Sullivan Street and Oliver Street.

Traffic Operations—Design year (2030) Build condition traffic volumes for the study area roadways were determined by estimating site-generated traffic volumes and distributing these volumes over study area roadways within Easton. These site generated volumes were added to the No-Build traffic volumes to create the 2030 Build condition traffic volume networks, which are depicted in Figures 4.1-66 and 4.1-67.

The projected number of vehicle trips in and out of the North Easton and Easton Village stations during the morning and evening peak hours are shown in Table 4.1-81. No park-and-ride trips are projected at Easton Village because no commuter parking is planned for that station, however 12 spots will be dedicated for kiss & ride accommodations within an existing private lot. The trip generation for the North Easton station is based on projected ridership on the Stoughton Alternative.

Table 4.1-81 Park-and-Ride and Vehicular Drop-Off Vehicle Trips:[1] Easton Stations (Stoughton and Whittenton Alternatives)

		Morning Peak Hour		Evening Peak Hour	
Station	**Type of Trip**	**In**	**Out**	**In**	**Out**
North Easton	Park-and-Ride	239	31	27	234
	Drop-off	27	27	26	26
	Total Vehicles	266	58	53	260
Easton Village	Park-and-Ride	0	0	0	0
	Drop-off	44	44	32	32
	Total Vehicles	44	44	32	32

1 The number of park-and-ride vehicle trips is calculated by dividing the number of park-and-ride riders by a 1.05 vehicle occupancy rate (VOR). The number of drop-off vehicle trips assumes one rider per vehicle.

The directional distribution of station-generated traffic is a function of population distribution, vehicle-owning households, existing travel patterns on area roadways, and traffic conditions. The trip distribution for the park-and-ride trips associated with North Easton Station is based on ridership data

provided by CTPS, which take into account these factors. Table 4.1-82 provides the geographic distribution of these trips.

Table 4.1-82 Easton Trip Distribution (Stoughton and Whittenton Alternatives)

To/From	Distribution
North	25%
South	18%
East	25%
West	32%

Source: CTPS Travel Demand Model.

The park-and-ride traffic was distributed to the study area roadways based on these percentages. Drop-off traffic was added separately and is based on existing travel patterns on area roadways near the proposed station locations. Only drop-off traffic was generated by Easton Village Station.

The intersection levels of service based on the addition of rail related traffic are shown in Table 4.1-83.

Source: Synchro 7.0 Software; Build 763
1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
4 average control delay for the critical movement, rounded to the nearest whole second, for unsignalized intersections
L = Left-turn; T = Through; R = Right-turn; All = All movements
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Two signalized and two unsignalized locations were analyzed for the North Easton station under Build conditions. The signalized intersection of Roche Bros Way and Route 138, which provides access to the train station, would operate at acceptable levels of service during both the morning and evening peak hours. The other three locations would operate at LOS E or F. Two signalized and three unsignalized locations were analyzed for the Easton Village station. The signalized intersection of Route 138 at Belmont Street would decline to a deficient LOS, from LOS D to LOS E, during the morning peak hour and remain at LOS F during the evening peak hour. Only one change in LOS is expected at the unsignalized locations; Lincoln Street at Barrows Street is expected to become deficient, declining from LOS D under No-Build to LOS F for Build conditions.

Traffic Signal Warrants—Three intersections were evaluated against the traffic signal warrant for the peak hour period:

- Route 138 at Elm Street
- Route 138 at Union Street
- Main Street at Center Street

The intersections of Route 138 at Elm Street and Route 138 at Union Street meet the requirements set forth by the MUTCD for traffic signal installation based on future peak hour traffic volumes.

The Main Street at Center Street intersection is projected to meet peak hour traffic signal warrants with or without the South Coast Rail project. With the adjacent historic Rockery, a Civil War memorial, a traffic signal system with the required lane configurations cannot be installed, as impacts to the historic property could not be avoided.

Pedestrians and Bicycles—The travel demand and ridership estimates completed by CTPS indicate that about 180 pedestrian/bicycle trips would access North Easton Station (Stoughton and Whittenton Alternatives) on a daily basis, which would increase pedestrian and bicycle activity in the vicinity of Route 138. At Easton Village Station (Stoughton and Whittenton Alternatives), approximately 240 pedestrian/bicycle trips would be expected. The majority of the infrastructure needed to support pedestrian and bicycle access to both proposed stations exists currently and would not be adversely impacted by the change in number of pedestrians on study area roadways.

The intersections of Route 138 at Elm Street and Route 138 at Union Street meet the requirements set forth by the MUTCD for traffic signal installation based on future peak hour traffic volumes.

The Main Street at Center Street intersection is projected to meet peak hour traffic signal warrants with or without the South Coast Rail project. With the adjacent historic Rockery, a Civil War memorial, a traffic signal system with the required lane configurations cannot be installed, as impacts to the historic property could not be avoided.

Traffic signal timing and phasing changes would be required at the North Easton Station driveway intersection with Route 138 to accommodate pedestrian demands. Pedestrian phases would also be included at the newly signalized intersections of Route 138 at Elm Street and Route 138 at Union Street. These changes are discussed further in Section 4.1.5, Mitigation Measures.

To accommodate increased pedestrian demand at Easton Village Station, crosswalks would be restriped at the intersections of Main Street at Center Street, Lincoln Street at Barrows Street, and Main Street at Barrows Street. At the Main Street at Center Street intersection, a high visibility crosswalk with a passive flashing pedestrian crossing sign would also be installed at the Main Street crosswalk. Sidewalks and crosswalks elsewhere in the vicinity of Easton Village Station are adequate to handle the expected demand.

Neither of the proposed station locations would physically alter designated bicycle facilities nor disrupt future plans for either on-road or off-road facilities in the study area. To accommodate demand, bicycle parking and storage locations would be maximized using available space.

Parking—The North Easton Station (Stoughton and Whittenton Alternatives) is proposed to have 509 parking spaces (12 of these handicapped accessible). The proposed project would not physically alter the existing public parking supply or impact parking availability within Easton in the vicinity of the North Easton Station. Based on the projected daily park-and-ride trips, the peak parking demand for North Easton Station is 520 spaces.

Ten vehicular drop-off parking spaces are proposed at Easton Village Station (Stoughton and Whittenton Alternatives). These parking spaces would be shared with the Easton Historical Society. The existing on-street parking supply in the vicinity of Easton Village is vulnerable to unauthorized use by commuters. Parking limit signage and increased enforcement may be needed to ensure parking is being properly utilized.

Raynham Transportation Impacts (Stoughton and Whittenton Alternatives)

The Raynham Park Station site (Stoughton and Whittenton Alternatives) is west of Route 138 just south of the Raynham-Taunton Greyhound Park. Access for all users would be provided via a newly signalized intersection with Robinson Road. Robinson Road would be realigned slightly to the north to create a four-way intersection with the station driveway.

Traffic Operations—Design year (2030) Build condition traffic volumes for the study area roadways were determined by estimating site-generated traffic volumes and distributing these volumes over study area roadways within Raynham. These site-generated volumes were added to the No-Build traffic volumes to create the 2030 Build condition traffic volume networks, which are shown in Figures 4.1-68 and 4.1-69.

The projected number of vehicle trips in and out of the Raynham Park Station (Stoughton and Whittenton Alternatives) during the morning and evening peak hours is shown in Table 4.1-84. The trip generation for this station is based on ridership projections for the Whittenton Alternative which generates the highest ridership projections for the Raynham Park Station.

The directional distribution of station-generated traffic is a function of population distribution, vehicle-owning households, existing travel patterns on area roadways, and traffic conditions. The trip distribution for the park-and-ride trips associated with the Raynham Park Station is based on ridership data provided by CTPS, which take into account these factors. Table 4.1-85 provides the geographic distribution of these trips.

Table 4.1-84 Park-and-Ride and Drop-off Vehicle Trips:[1] Raynham Park Station (Stoughton and Whittenton Alternatives)

		Morning Peak Hour		Evening Peak Hour	
Station	Type of Trip	In	Out	In	Out
Raynham	Park-and-Ride	183	21	17	166
	Drop-off	32	32	25	25
	Total Vehicles	215	53	42	191

1 The number of park-and-ride vehicle trips is calculated by dividing the number of park-and-ride riders by a 1.05 vehicle occupancy rate (VOR). The number of drop-off vehicle trips assumes one rider per vehicle.

Table 4.1-85 Raynham Park Station Trip Distribution (Stoughton and Whittenton Alternatives)

To/From	Distribution
North	5%
South	31%
East	15%
West	49%

Source: CTPS Travel Demand Model.

The park-and-ride traffic was distributed to the study area roadways based on these percentages. Drop-off traffic was added separately and is based on existing travel patterns on area roadways near the proposed station locations.

The intersection levels of service based on the addition of rail related traffic are shown in Table 4.1-86. All six signalized intersections would continue to operate at acceptable levels of service under Build conditions. There would be no change in levels of service at two of the three unsignalized intersections. During the morning peak hour, the intersection of Route 138 at Wilbur Street would decline from LOS E under No-Build to LOS F. Operations during the evening would remain unchanged. The unsignalized intersection of the existing driveway with Route 138, which would also serve as the station driveway, would continue to operate at LOS F. The operational discussion of the proposed traffic signal at Route 138 and Robinson Street/Station Driveway is discussed in Section 4.1.5, Mitigation Measures.

1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
4 average control delay for the critical movement, rounded to the nearest whole second, for unsignalized intersections
L = Left-turn; T = Through; R = Right-turn
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Traffic Signal Warrants—Two intersections for the Raynham Park Station (Stoughton and Whittenton Alternatives) were evaluated against the traffic signal warrant for the peak hour period:

- Route 138 at Station Driveway
- Route 138 at Wilbur Street

The intersection of Route 138 at the proposed Station Driveway meets the requirements set forth by the MUTCD for traffic signal installation based on future peak hour traffic volumes. The Route 138 at Wilbur Street intersection does not meet peak hour traffic signal warrants based on the projected future traffic volumes.

Pedestrians and Bicycles—The travel demand and ridership estimates completed by CTPS indicate that about 140 pedestrian/bicycle trips would access Raynham Park Station (Stoughton and Whittenton Alternatives) on a daily basis, which would increase pedestrian activity along Route 138 and within the neighborhood to the east of Route 138. To accommodate pedestrian demands, a pedestrian phase would be incorporated into the signalized station driveway entrance to the site. Installation of this signal also requires the realignment of Robinson Street slightly to the north. It is expected that the crossing

and roadway realignment would encourage the use of Robinson Street, a low volume roadway, as a pedestrian route rather than the more congested Route 138.

The proposed station location would not physically alter designated bicycle facilities or disrupt future plans for either on-road or off-road facilities in the study area. To accommodate demand, bicycle parking and storage locations would be maximized using available space.

Parking—Raynham Park Station (Stoughton and Whittenton Alternatives) is proposed to have 448 parking spaces (of which eight would be handicapped accessible). An additional seven parking spaces would be reserved for drop-off activity. The proposed project would not physically alter the existing public parking supply or impact parking availability within Raynham. Based on the projected daily park-and-ride ridership, the parking supply would be sufficient to meet the peak parking demand for 400 spaces.

Layover Facilities

The proposed overnight layover facilities would only generate traffic associated with MBTA personnel. Due to the low number of trips anticipated, any impacts on traffic would be negligible and do not warrant detailed analysis.

Temporary Construction Impacts

The Build Alternatives have the potential to cause temporary disruptions in local access and mobility during the construction period as a result of temporary street closures and detours. Temporary street closures could be required to make improvements to the grade-crossings, such as new crossing gates, modifications to intersections and construction of stations. Construction activities would also generate additional traffic related to construction employee commutes, and the transport of materials and equipment by truck. As part of that phase, MassDOT will develop transportation management plans to detour traffic around construction areas. These transportation management plans will be closely coordinated with the cities and towns affected by each construction element, including emergency response representatives. A robust outreach program would be developed, notifying the public of construction activities through telephone calls, email blasts, website notices, and flyer distributions. Public information meetings would be conducted, identifying bridge construction and roadway closure locations, intersection construction activities, construction schedules, and temporary traffic, safety, and pedestrian detours through construction areas. For additional information on the construction staging plans, refer to Appendix 3.2-F.

4.1.5 Mitigation Measures

This section discusses safety and mitigation measures associated with grade crossing impacts. In addition, the LOS results completed as part of the Build impact analysis identify locations where the proposed stations are likely to cause traffic operations on the local roadway network to degrade. Specific mitigation measures that could be undertaken by MassDOT, as discussed below, were developed to offset these impacts and ensure adequate access to the proposed stations. In the case where structural changes to the roadway and traffic control devices are proposed, the mitigation aims to improve traffic flow with minimal impacts to adjacent land uses and at reasonable cost. The benefit of these changes is noted in the discussions below. The traffic mitigation measures are presented by municipality and station.

4.1.5.1 Grade Crossings

The following components and characteristics are being considered to optimize safety at the proposed South Coast Rail at-grade crossings:

- **Vehicle Type and Condition**. At-grade crossings would be designed to anticipate different vehicle types (passenger cars, trucks, buses). All rail vehicles would be required to undergo frequent inspection programs to ensure each vehicle in active service is maintained to meet current safety standards in an effort to remove the possibility of equipment or materials falling off the vehicles at grade crossings, or the vehicles from breaking down in an at-grade crossing.

- **Geometry**. At-grade crossings would be designed with minimum curvature or profile changes to allow for optimal sight lines, allowing drivers more time to safely stop before the crossing. Some existing at-grade crossings would be closed in some locations to optimize safety, as noted in Section 4.1.4, Proposed At-Grade Crossings.

- **Signage and Markings**. All traffic control devices (such as highway signage, markings and devices, etc.) would be designed in compliance with the MUTCD[16]. Signs and markings would be placed a sufficient distance from the crossings to allow adequate warning to motorists and pedestrians.

- **Crossing Surface**. The condition of the roadway in the vicinity of the at-grade crossing and the condition of the track would be maintained at existing standards by maintaining the road surface and rail seal.

- **Site Conditions.** Physical obstructions in the vicinity of each crossing, such as trees and vegetation, buildings, signal cases and bungalows, signs, hills, fences, walls and parked vehicles, would be minimized or eliminated to provide drivers with optimal sight lines.

- **Illumination.** Visibility of the train and the general visibility of an at-grade crossing are important elements that would be considered. Methods for illumination would include lights and reflectorization of the train, and/or lighting at the at-grade crossings (i.e. street lights).

- **Traffic Signal Preemption.** Where a signalized intersection is located within 200 feet of an at-grade crossing, traffic signal preemption would be used to ensure that vehicle queues are cleared in advance of the train.

- **Signals and Operations.** A traditional at-grade crossing is made up of several types of warning devices. A bell serves as an audible warning that the gates would begin their downward track. At the same time the bell is initiated, the flashers both on the flasher pole and the gate arm are activated. This is a visual warning for the motorist that the gates would begin their descent. The MUTCD requires a minimum of 20 seconds of warning time at at-grade crossings. Both of these would be used to ensure proper visual and audible warnings for motorists.

[16] US Department of Transportation. Federal Highway Transportation. *Manual on Uniform Traffic Control Devices for Street and Highways*. May 2012. Web. Apr.-May 2012. <http://mutcd.fhwa.dot.gov/pdfs/2009r1r2/mutcd2009r1r2edition.pdf>

- **Gated Warning Devices.** Commonly used throughout the country. The gates are made out of a fiberglass resin, which is designed to break away should emergency vehicles or other vehicles need to drive through the gates. Gated crossings are typically outfitted with flasher units and bells for visual and audible warning devices.

- **Gate Timing.** Traditionally, railroad and transit agencies allow for 30 seconds of warning time, an additional 10 seconds over the MUTCD's requirements. This is generally due to varying conditions at an at-grade crossing, including gate lengths, wind conditions, weather condition and varying maintainer adjustments. This allowance would be used at at-grade crossings for the South Coast Rail project.

- **Vital Logic.** Vital railroad signal logic, equipment that identifies the train speed and location through circuitry in the rails and onboard computers in the locomotive, would be used at at-grade crossings to identify the direction of an approaching train, identify any hazards in the crossing, and create a failsafe that would close the gates automatically in the event of an emergency.

- **AHCW Systems.** Each proposed public and private at-grade crossing would be suitable for public use if equipped with a combination of new, state-of-the-art, Automatic Highway Crossing Warning (AHCW) systems and designed with minor geometric modifications (such as driveway reconfiguration, driveway closures, vegetation clearing and utility pole relocations). The advanced warning system would communicate with the MBTA Operational Control Center (OCC) and would allow MBTA train dispatchers to communicate with and receive indications directly from each at-grade crossing.

- **General Safety Enhancements.** Recommended at all South Coast Rail at-grade crossings that are proposed to remain active. These measures include:

  - Remove gates and signals at existing crossings and replace them with new gates, signals, and signal cases;

  - Remove vegetation at all at-grade crossings to improve sight distance;

  - Evaluate the need for guardrails at each location during final design; and

  - Evaluate the need to remove or relocate utility poles, walls, boulders and fences during final design.

In addition to the general improvements listed above, additional site specific improvements are recommended. These improvements range from minor (installing traffic signal pre-emption at existing intersections) to major construction (potential at-grade separation). These recommended improvements are summarized in Table 4.1-87 and briefly described subsequently.

Table 4.1-87 Stoughton Alternatives Proposed At-Grade Crossing Improvements

Town/City	Street	Recommended At-Grade Crossing Safety Improvements
STOUGHTON LINE		
Canton	Washington Street	Install a traffic signal pre-emption system at two intersections in proximity of the crossing
	Pine Street	Relocate existing driveway to the north
	Will Drive	General improvements
Stoughton	Central Street	Relocate existing driveway to the west
		Coordinate crossing operation with fire station located 400 feet west
		Extend sidewalk through the crossing
		Install crosswalk across the Central Street eastbound approach to the crossing
	Simpson Street	General improvements
	School Street	Modify alignment at Cushing Street
	Porter Street (Route 27)	General improvements
	Wyman Street	Reconfigure parking lot and driveway
	Brock Street	Investigate installation of a traffic signal with pre-emption system at nearby intersection
		Reconfigure driveway to the east and relocate driveway to the west
	Plain Street	Investigate installation of a traffic signal with pre-emption system at nearby intersection
		Relocate driveways to the east
	Morton Street	Close Morton Street
		Construct frontage road to Totham Farm Road
Easton	Elm Street	Relocate driveway to the east
	Oliver Street	Relocate driveways to the northwest
		Relocate children’s play area
		Extend sidewalk through crossing
	Gary Lane	Install gates and locks
	Short Street	General improvements
	Depot Street (Route 123)	Reconfigure driveway to the west
	Purchase Street	General improvements
	Prospect Street	General improvements
	Foundry Street (Route 106)	General improvements
Raynham	Race Track Crossing	General improvements
	Elm Street	General improvements
	Carver Street	Reconstruct culvert
	Broadway (Route 138)	At-grade separation
	Britton Street	General improvements
	King Philip Street	Relocate driveways
	East Britannia Street	General improvements
Taunton	Longmeadow Road	Reconfigure or close driveways
	Dean Street (Route 44)	Reconstruct Dean Street/Arlington Street traffic signal system
		Install traffic pre-emption phasing at Dean Street/Arlington Street
NEW BEDFORD MAIN LINE		
	Ingell Street	Close driveway to the west

Town/City	Street	Recommended At-Grade Crossing Safety Improvements
	Hart Street	General improvements
Berkley	Cotley Street	General improvements
	Padelford Street	General improvements
	Myricks Street (Route 79)	General improvements
Lakeville	Malbone Street	General improvements
Freetown	Chace Road	Reconfigure or close driveway to the west
	Braley Road	General improvements
	East Chipaway Road	General improvements
New Bedford	Samuel Barnet Road	General improvements
	Pig Farm Road	General improvements
	Tarkiln Hill Road	Close Tarkiln Hill Road and reroute traffic through Stop & Shop driveway
		Signal pre-emption at King's Highway / Stop & Shop driveway
		Signal pre-emption at Tarkiln Hill Road / Church Street
		At-grade crossing pre-signals
	Nash Road	Signal pre-emption at Church Street / Nash Road
		At-grade crossing pre-signals
FALL RIVER SECONDARY		
Berkley	Mill Street	Close crossing
	Adams Lane	Close crossing
Freetown	Beachwood Road	Close crossing
	Richmond Road/Route 79 (North)	General Improvements
	Richmond Road/Route 79 (South)	Reconfigure driveway to the west
	Forge Road (North)	Close Forge Road
	Forge Road (South)	General improvements
	Elm Street	General improvements
	High Street	General improvements
	Copicut Road	General improvements
	Brightman Lumber	General improvements

The specific improvements within each municipality under the Stoughton Alternatives are described below. Except for the Longmeadow Rd. and Dean St. (Route 44) crossings in Taunton, these crossings are also part of the Whittenton Alternatives.

- **Canton**. Three at-grade crossings (Washington Street, Pine Street, and Will Drive) are located in Canton along the active commuter rail line. The construction of a second track along this section of the alignment and increased train activity would not result in substantial changes in traffic conditions or queue lengths at these crossings. As part of the proposed South Coast Rail project, traffic signal preemption is recommended at the intersection of Washington Street and Revere Street to address queuing that may extend over the tracks during the peak hours.

- **Stoughton**. Eight public at-grade crossings in Stoughton would be affected. Five of these at-grade crossings (Central Street, Simpson Street, School Street, Porter Street, and Wyman

Street) are active commuter rail at-grade crossings that would be modified to allow double-track operations. The addition of a second track and additional trains would result in negligible changes in traffic conditions or queue lengths at these crossings. A sixth crossing, at Brock Street, is considered active and has working signals but is rarely used today. For the purposes of this analysis, Brock Street is considered a reactivated crossing. A seventh crossing is proposed at Plain Street. An existing at-grade crossing at Morton Street would be closed and traffic would be rerouted to a proposed street that would run parallel to the proposed track and cross to the south underneath the track at a bridge.

- **Easton**. Eight currently inactive public at-grade crossings are located in Easton. All of the crossings in Easton would be reactivated as part of the South Coast Rail project. The Main Street crossing is currently grade separated and a new bridge that passes over the rail right-of-way will be constructed. A previous bridge at this location has been filled in; therefore, the new bridge would either be constructed on new abutments or the existing abutments that remain, and the embankment excavated to track grade below.

- **Raynham**. Six public at-grade crossings and one private crossing, all inactive, are located in Raynham. Five public at-grade crossings would be reactivated as part of the South Coast Rail project. The private crossing at the Race Track would also be reactivated as part of the South Coast Rail project. A sixth public at-grade crossing, across Broadway (Route 138), is projected to have relatively high traffic volumes and is recommended for at-grade separation to minimize traffic impacts along this section of Route 138.

- **Taunton.** Four public at-grade crossings are located in Taunton. Both the Ingell Street and Hart Street crossings are currently active crossings with freight train activity. These crossings would be upgraded to accommodate the proposed commuter rail trains. The at-grade crossing at Longmeadow Road would be reactivated as part of the South Coast Rail project. The Dean Street (Route 44) at-grade crossing is active with freight rail activity a few times a week. Similarly to Main Street, the Thrasher Street crossing is currently grade separated and a new bridge that passes over the rail right-of-way will be constructed. A previous bridge at this location has been filled in; therefore, the new bridge would either be constructed on new abutments or the existing abutments that remain, and the embankment excavated to track grade below.

- **Berkley.** Four existing public at-grade crossings and one private at-grade crossings are located in Berkley. Cotley Street, Padelford Street, Myricks Street (Route 79), and Mill Street currently carry active freight traffic. Mill Street is proposed to be closed. The three other crossings would be upgraded to accommodate the proposed commuter rail trains. Adams Lane, a private at-grade crossing, is also proposed to be closed

- **Lakeville.** One public at-grade crossing is located in Lakeville. The crossing at Malbone Street currently carries active freight traffic. This crossing would be upgraded to accommodate the proposed commuter rail trains.

- **Freetown.** Ten public at-grade crossings, two of which have a northern and southern section, and one private at-grade crossing in Freetown currently carry active freight traffic. The northern part of Forge Road would be closed and the remaining ten crossings would be

upgraded to accommodate the proposed commuter rail trains. Seven of these crossings are expected to cause minor delays and have little impact on the surrounding roadways.

- **New Bedford.** Three public at-grade crossings (Samuel Barnet Road, Tarkiln Hill Road, and Nash Road) and one private at-grade crossing (Pig Farm Road) currently carry active freight traffic and would be upgraded to accommodate the proposed commuter rail service.

- **Fall River.** There are no at-grade crossings in Fall River. All major street crossings within Fall River are grade-separated and all remaining private roadways crossings are expected to be closed.

Additional mitigation commitments specific to the Attleboro Secondary portion of the Whittenton Alternatives are summarized in Table 4.1-88. The Bay Street crossing is currently grade separated. The Bay Street Bridge has been filled in and would need to be reconstructed to provide adequate track clearance for the rail service. A new superstructure would be constructed on new abutments and the embankment fill excavated below to the proposed track grade.

Table 4.1-88 Attleboro Secondary Recommended Grade Crossing Mitigation Improvements (Whittenton Alternatives)

Town/City	Street	Recommended At-Grade Crossing Safety Improvements
Taunton	Tremont Street	Reconfigure driveway to the north
	Oak Street	Optimize existing pre-emption at Oak Street / Tremont Street
	Porter Street	Reconfigure driveway to the east
	Cohannet Street	Reconfigure or close driveways adjacent to the tracks
	Winthrop Street	Additional advance RR warning signs
	Somerset Avenue	Investigate installation of a traffic signal with pre-emption system at nearby intersection
	Weir Street	Close McSoley Street
		Close and reconstruct driveway to the west
		Close and reconstruct driveway to the east

MBTA Grade Crossing Safety Policies and Programs

MBTA Safety Department officials are regularly in the field inspecting stations, buses, subways, commuter rail and boats to ensure a safe environment. All stations and vehicles have direct communication lines to the MBTA's Operations Control Center and stations are being upgraded with modernized public address systems and closed-circuit television camera systems. MBTA personnel are trained in emergency response and their safety program (coordinated with local, state, federal law enforcement agencies, as well as the MBTA Police) includes a schedule of simulated emergency response exercises geared toward preparing MBTA personnel to be equipped with state-of-the-art emergency response techniques.

The MBTA Safety Department tracks all accidents and incidents throughout the MBTA system and is responsible for reporting all required safety and security data to the National Transit Database (NTD)17 and the Department of Public Utilities (DPU). The NTD is maintained by the Secretary of Transportation, per Title 49 U.S.C. 5335(a) SECTION 5335 National transit database. This data is used by the MBTA to measure safety on the MBTA and by the Federal Transit Administration (FTA) to track incident trends in the industry. The MBTA posts a monthly incident report on their public website. NTD reportable incidents are also posted on the NTD website at: http://www.ntdprogram.gov/ntdprogram/.

In order to minimize incidents within the system, the MBTA Safety Department has undertaken and/or maintains the following measures:

- Performs routine safety audits of all transit stations to note and correct safety hazards.
- Increased the number of track and platform audits.
- Performs audits of tunnel lighting.
- Established a zero tolerance policy pertaining to use of cell phones and all other electronic devices while operating an MBTA vehicle.
- Established the Safety and Operations Rules Compliance Program, which has performed over 2000 safety observations.

Commuter Rail Safety Education

Similar to the MBTA Greenbush Line project, the South Coast Rail project will require a comprehensive grade-crossing safety awareness program.

The MBTA will educate the public using the "Operation Lifesaver" program at least one year prior to the scheduled revenue operation date. "Operation Lifesaver" is a national non-profit organization whose program is available to any transit agency who is seeking to improve safety and education for communities that contain rail traffic. The program's railroad safety information and specially trained personnel can be used to train others to educate communities. The primary focus of the program is to communicate the importance of railroad public awareness, the potential hazards at highway/rail at-grade crossings, and the dangers of trespassing on railroad right-of-way.

During the design and early construction phases of the South Coast Rail project, the MBTA will:

- Train various groups and individuals, including students and community organizations, police officers, fire fighters, school officials, and agency staff.
- Conduct direct public contact through marketing, presentations, mass mailing, press releases, and conducting special safety fairs in every affected city and town.
- Training fire fighters and emergency response personnel in Emergency Evacuation Procedures.

[17] Title 49 U.S.C. 5335(a): SECTION 5335 National transit database. http://www.ntdprogram.gov/ntdprogram/ntd.htm.

4.1.5.2 Stations

New Bedford (Both Rail Alternatives)

The following intersection improvements are required to mitigate existing deficiencies at critical locations or adverse impacts caused by the alternatives. Table 4.1-89 presents a comparison of Build Alternatives without and with mitigation operations to illustrate the benefit of the proposed mitigation. The Mitigation associated with the Whale's Tooth and King's Highway stations are proposed as part of the Whittenton and Stoughton Alternatives.

Whale's Tooth Station Area Traffic Mitigation (Both Rail Alternatives)

Acushnet Avenue at Hillman Street—A pedestrian crosswalk is proposed at this location to accommodate the projected pedestrians. The crosswalk would be installed across the southern Acushnet Avenue approach to the intersection and provide a connection to the station from the residential area located to the west of Route 18.

Acushnet Avenue Sidewalk—Installation of a 6-foot wide sidewalk along the eastern side of Acushnet Avenue is proposed to complete the pedestrian connection from Hillman Street. The 300-foot long sidewalk would be between Hillman Street and the proposed station driveway.

Table 4.1-89 New Bedford Intersection Capacity Analysis –2030 Build with Mitigation Conditions vs. 2030 Build Conditions

	Weekday Morning Peak Hour				Weekday Evening Peak Hour			
	Build	Build with Mitigation			Build	Build with Mitigation		
Signalized Intersections	LOS[1]	V/C[2]	Delay[3]	LOS	LOS	V/C	Delay	LOS
Whale's Tooth Station								
Mill Street at Pleasant Street	F	0.76	47	D	E	0.93	64	E
Coggeshall Street at N. Front Street[4]	F	0.66	12	B	F	0.71	14	B
Coggeshall Street at Purchase Street[4]	F	0.53	13	B	F	0.62	14	B
King's Highway Station								
King's Highway at Route 140 NB Ramps	C	0.60	20	C	C	0.89	29	C
Church Street at Tarkiln Hill Road	C	0.74	24	C	D	0.79	29	C
King's Highway at Stop & Shop Driveway	A	0.52	9	A	B	0.82	29	C
King's Highway at King's Highway Station (Shaw's) Driveway	A	0.41	6	A	A	0.55	9	A
King's Highway at Mt. Pleasant Street	C	0.54	24	C	E	0.93	42	D

Source: Synchro 7.0 Software; Build 763
1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
4 Unsignalized in the Build condition
L = Left-turn; T = Through; R = Right-turn; All = All movements
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Mill Street at Pleasant Street and Kempton Street—Signal timing adjustments are proposed to accommodate project related pedestrians and traffic at this location. Signal timing changes would be made to provide a longer crossing interval for the exclusive pedestrian phase. The proposed mitigation at this location would improve operations to LOS D during the morning peak hour.

Coggeshall Street at North Front Street—This unsignalized intersection processes a high amount of traffic and operates at LOS F during the morning and evening peak hours with or without the project. To offset project related traffic at this intersection, a traffic signal would be installed. The proposed signal would be designed to operate with two phases, the first phase servicing Coggeshall Street and the second phase for North Front Street.

Pedestrian crossings would occur concurrently with these phases. With the proposed improvement, the intersection of Coggeshall Street at North Front Street would operate at LOS B during both the morning and evening peak hour.

As Coggeshall Street is under the jurisdiction of the City of New Bedford, any improvements to this intersection will require review and authorization by the City of New Bedford. Should these improvements be desired, MassDOT could contribute to the construction or implementation of these intersection improvements based on their fair share of the impacts to the intersection.

Coggeshall Street at Purchase Street—This unsignalized, all-way STOP controlled intersection processes a high amount of traffic and operates at LOS F during the evening peak hour with or without the project. To improve the identified safety issues at this location as well as offset project related traffic impacts, a traffic signal would be installed at this location. The proposed signal would be designed to operate with three phases, the first phase servicing Purchase Street and the second phase exclusively for pedestrian crossings and the third phase for Coggeshall Street. With the proposed improvement, the intersection of Coggeshall Street at Purchase Street would operate at LOS B during both the morning and evening peak hour.

As Coggeshall Street is under the jurisdiction of the City of New Bedford, MassDOT has coordinated the design of this intersection with the city as part of the *Freight Railroad Bridge Improvement Project, Rehabilitation of Bridges over Deane Street, Sawyer Street, and Coggeshall Street*. This bridge rehabilitation project, which is functionally independent of the South Coast Rail project, received $20 million in Transportation Infrastructure Generating Economic Recovery (TIGER) federal funding, part of which will help improve the signal at Deane Street at Purchase Street and install new signals at the intersections of Purchase Street at Sawyer Street and Purchase Street at Coggeshall Street.

King's Highway Station Traffic Mitigation (Both Rail Alternatives)

King's Highway Corridor—To accommodate project traffic, interconnection and coordination of the traffic signals along King's Highway is proposed. Signal controller upgrades, interconnection infrastructure (conduit/cable), signal timing and phasing improvements would be required at the following locations:

- Mount Pleasant Street at Jones Road/King's Highway
- King's Highway at Shaw's Driveway
- King's Highway at Route 140 Northbound Ramps

- King's Highway at Stop & Shop Driveway
- Tarkiln Hill Road at Church Street

Mount Pleasant Street at Jones Road/King's Highway—To improve traffic operations and pedestrian crossing times at this location, traffic signal phasing would be revised to provide a permissive eastbound/westbound phase. Traffic signal timings would be modified to support the new phasing. Signal timing and phasing changes will allow this intersection to return to acceptable traffic operations during the evening peak hour.

King's Highway at Shaw's Driveway—To facilitate pedestrian movements at this intersection a crosswalk would be provided across the Shaw's Driveway entrance. Concurrent pedestrian phasing would be provided to facilitate the pedestrian crossing. During the evening peak hour, traffic operations degrade from LOS A to LOS B in order to accommodate pedestrians. However, the intersection would still operate at an acceptable LOS during both peak hours.

King's Highway at Stop & Shop Driveway—Several changes are recommended for this location due to its proximity to the King's Highway grade crossing. The traffic signal would be modified to allow for traffic signal pre-emption when the train approaches the station. Should the vehicle queue along King's Highway extend over the railroad tracks, the signal would operate such that the queue would clear prior to the train's arrival. Pre-signals would be required at the grade crossing to support this movement and prevent additional traffic from driving over the railroad tracks.

The intersection of Tarkiln Hill Road and King's Highway would be closed for safety purposes due to its proximity to the grade crossing. As shown on Figure 4.1-70, traffic currently turning into or out of Tarkiln Hill Road at this location would be diverted to Stop & Shop and enter Tarkiln Hill Road at the back of the property. Approximately 24 parking spaces associated with the Stop & Shop Plaza and Wendy's Restaurant would be impacted by this diversion of Tarkiln Hill Road. To maintain the fastest possible emergency response times, mountable curbing would be used to close the exiting intersection. In the event of an emergency, this curbing could be driven over by emergency responders.

Tarkiln Hill Road at Church Street—A concurrent pedestrian crossing phase is proposed for the intersection of Tarkiln Hill Road at Church Street. Signal timing changes would be required to accommodate pedestrian movements, but LOS would not be affected during either peak hour.

Similar to King's Highway at Stop & Shop Driveway, the traffic signal would also be modified to allow for traffic signal pre-emption when the train approaches the station. Pre-signals at the grade crossing would support this movement and prevent additional traffic from driving over the railroad tracks.

Freetown Station Area Traffic Mitigation (Both Rail Alternatives)

The following three pedestrian-related improvements are suggested to improve connectivity between residential areas within walking distance to the proposed Freetown Station. Freetown Station is proposed as part of the Whittenton and Stoughton Alternatives.

South Main Street

To facilitate pedestrian travel from the north, construction of a 6-foot sidewalk is proposed on the east side of South Main Street from the existing sidewalk's terminus at Stop & Shop to the station driveway (approximately 1,600 feet).

South Main Street at Narrows Road

The existing crosswalk across South Main Street at Narrows Road is proposed to be restriped. As part of this improvement, ADA/AAB compliant wheelchair ramps would be constructed at this location.

South Main Street at Copicut Street

A pedestrian crosswalk is proposed at this location. The crosswalk would be installed across Copicut Street on the east leg of the intersection. Compliant ADA/AAB wheelchair ramps are also proposed.

Fall River Station Area Traffic Mitigation (Both Rail Alternatives)

The following three intersection improvements are suggested to mitigate existing deficiencies at critical locations or adverse impacts caused by the alternatives. Table 4.1-90 presents a comparison of Build to Build with mitigation operations to illustrate the benefit of the proposed changes. Both Fall River Stations are proposed as part of the Whittenton and Stoughton Alternatives.

Table 4.1-90 Fall River Intersection Capacity Analysis–2030 Build with Mitigation Conditions vs. Build Conditions (both alternatives)

	Weekday Morning Peak Hour				Weekday Evening Peak Hour			
	Build	Build with Mitigation			Build	Build with Mitigation		
Signalized Intersections	LOS[1]	V/C[2]	Delay[3]	LOS	LOS	V/C	Delay	LOS
Fall River Depot Station								
President Avenue at N. Davol Street	B	0.62	26	C	C	0.84	32	C
N. Main Street at President Avenue	D	0.81	24	C	D	0.88	35	D

Source: Synchro 7.0 Software; Build 763
1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections

Fall River Depot Station Area Traffic Mitigation (Both Rail Alternatives)

North Main Street and President Avenue—Intersection geometry, signal timing and phasing improvements are proposed for this location to accommodate project related pedestrians and traffic and mitigate existing safety problems. Crash data indicate a high number of angle crashes occur at this intersection. Slight widening of the North Main Street approaches is proposed to provide exclusive left-turn lanes and through-right-turn lanes. In addition, signal phasing would be revised to provide protected/permissive left-turn phasing for the westbound approach. Signal timing changes would be made to accommodate the proposed phasing change and provide a longer interval for the exclusive pedestrian phase. The proposed mitigation at this location would improve the morning peak hour from LOS D to LOS C. The evening peak hour would remain at LOS D.

President Avenue at North Davol Street—Pedestrian crossing times would increase to accommodate project related pedestrians at this location, which would cause an adverse impact to overall vehicular traffic operations (i.e. increased delay) under every alternative during at least one peak hour. However, the intersection is projected to operate at acceptable levels of service with these pedestrian timing improvements.

Battleship Cove Station Area Traffic Mitigation (all alternatives)

Broadway at Central Street—No changes are proposed to traffic operations at this location. Existing crosswalks across Broadway and Central Street (under the viaduct) would be restriped to facilitate the pedestrian pathway between the neighborhood and the proposed Battleship Cove Station. As part of this measure, existing wheelchair ramps would be evaluated to determine whether they comply with the current standards as prescribed by the Americans with Disabilities Act (ADA) and the Architectural Access Board (AAB). Non-compliant wheelchair ramps would be redesigned based on the prevailing ADA/AAB guidance in affect at that time.

Taunton Station Area Traffic Mitigation

The following intersection improvements are required to mitigate existing deficiencies at critical locations or adverse impacts caused by the alternatives. Table 4.1-91 presents a comparison of Build to Build with mitigation operations to illustrate the benefit of the proposed changes. The Taunton Depot station is proposed as part of the Whittenton and Stoughton Alternatives.

Table 4.1-91 Taunton Depot Intersection Capacity Analysis–2030 Build with Mitigations Conditions vs. 2030 Build Conditions

	Weekday Morning Peak Hour				Weekday Evening Peak Hour			
	Build	Build with Mitigation			Build	Build with Mitigation		
Signalized Intersections	LOS[1]	V/C[2]	Delay[3]	LOS	LOS	V/C	Delay	LOS
Taunton Depot Station (all alternatives)								
Route 140 at Hart Street	E	>1.00	66	E	F	>1.00	73	E

Source: Synchro 7.0 Software; Build 763
1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
L = Left-turn; T = Through; R = Right-turn; All = All movements
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Taunton Depot Station Area Traffic Mitigation (Both Rail Alternatives)

Route 140 at Hart Street (Both Rail Alternatives)—The signal timing at the Route 140 and Hart Street intersection would be adjusted to reduce delays on the Hart Street approaches. This results in an improvement during the evening peak hour from LOS F to LOS E.

Sidewalk Improvements (Both Rail Alternatives)

To facilitate pedestrian travel from Route 140 to the station, construction of a 6-foot wide sidewalk is proposed on the north side of the Target Plaza parking lot from the terminus of Taunton Depot Drive's sidewalk to the station.

Dana Street Station Area Traffic Mitigation (Whittenton Alternatives)

Mitigation previously proposed in the DEIS/DEIR at the intersection of Route 140/Tremont Street at Oak Street was developed to support optimizing the grade crossing pre-emption timing at the Oak Street grade crossing. Although project impacts would be lower with the station on Dana Street, the mitigation measures are still being proposed to compliment adjacent grade-crossing improvements. Based on the projected traffic volumes, the Washington Street southbound approach would be reconfigured to provide an exclusive right-turn lane and a combined left turn/through lane. Traffic signal phasing would be revised to provide an overlap southbound right-turn phase during the Tremont Street eastbound phase. A longer crossing interval for the exclusive pedestrian phase would also be provided.

Due to the relocation of the station to Dana Street, additional mitigation measures are required. The existing crosswalks at the intersection of Route 140/Tremont Street and Granite Street should be restriped. Specialty (high visibility) materials should be considered for the crosswalk as it would provide a gateway to the station would likely get substantially more use than it does today. It does not appear that the proposed Dana Street Station would generate enough traffic such that a traffic signal would be warranted at the station driveway or at the intersection of Route 140/Tremont Street at Granite Street.

The Dana Street Station is proposed in a more residential area of Taunton than the previously proposed station. Traffic volumes along Danforth Street, Dana Street, Granite Street, Columbia Avenue, Hodges Avenue, and Morton Street would need to be monitored for cut-through traffic and speeds in order to alleviate the new flow in a residential area. Traffic calming mitigation plans may be needed to address these issues if and when the station opens to vehicular traffic.

Previously proposed traffic signal timing changes at the intersection of Washington Street and Court Street and a proposed traffic signal installation at the intersection of Washington Street at Frederick Martin Parkway are no longer being considered as part of the South Coast Rail project as they are no longer needed due to the lower numbers of, and a shift in, ridership.

Taunton Station Area Traffic Mitigation (Stoughton Alternative)

All mitigation measures related to Taunton Station that were proposed in the DEIS/DEIR are still recommended. Minor additional signal timing changes are needed at the intersection of Route 44 and Longmeadow Road. In addition to what was recommended in the DEIS/DEIR, based on new ridership estimates, mitigation measures at the intersection of Arlington Street and School Street were considered. Based on peak hour volume data, the intersection does not meet the peak hour traffic signal warrant. Consideration should be given to conversion of this two-way stop controlled intersection to an all-way stop controlled intersection to improve operations and safety.

Table 4.1-92 Signalized Intersection Traffic Operations–Build vs. Build with Mitigation

	2035 Weekday Morning Peak Hour				2035 Weekday Evening Peak Hour			
	Build	Build with Mitigation			Build	Build with Mitigation		
Signalized Intersections	LOS[1]	V/C[2]	Delay[3]	LOS	LOS	V/C	Delay	LOS
Broadway St at Washington St	D	0.70	28	C	E	0.90	51	D
Route 44 at Longmeadow Road	F	>1.00	74	E	F	>1.00	>80	F
Route 44 at Arlington Street	F	0.89	35	C	E	0.90	32	C

Source: Synchro 7.0 Software; Build 763
1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
L = Left-turn; T = Through; R = Right-turn; All = All movements
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Broadway at Washington Street (Stoughton Alternative)—The signal timing at the Broadway and Washington Street intersection would be adjusted to reduce delays on the Washington Street approaches during the evening peak hour. This timing adjustment results in an improvement during the evening peak hour from LOS F to LOS E.

Dean Street at Longmeadow Road (Stoughton Alternative)—Based on the projected traffic volumes, the Longmeadow Road southbound approach would be reconfigured to provide two general purpose lanes. Traffic signal timings would be modified to support revised signal timings and provide a longer crossing interval for the exclusive pedestrian phase. The increased pedestrian crossing times would cause an adverse impact to overall vehicular traffic operations (i.e. delay) during both peak hours. There is no opportunity at this location to increase capacity by adding lanes or changing lane allocation. However, once the project is in service, traffic and pedestrian signal timings would be further adjusted to balance the needs of pedestrians and motorists.

Dean Street at Prospect Street (Stoughton Alternative)—Proposed improvements at this intersection involve construction of ADA/AAB-compliant pedestrian ramps, new crosswalk and pavement markings across Dean Street. A passively-activated flashing pedestrian crossing sign would be installed at the Dean Street crosswalk. This sign, activated when a pedestrian entered a detection zone at the pedestrian ramps of the crossing, would highlight the location as an active pedestrian crossing to approaching motorists.

Dean Street at Arlington Street (Stoughton Alternative)—Improvements at this intersection would involve widening of the Arlington Street southbound approach to provide exclusive turning lanes and reconstruction of the existing traffic signal system in order to coordinate with the proposed gate and railroad signal improvements at the adjacent grade crossing. Signal timing and phasing changes will allow this intersection to remain at acceptable traffic operations during both peak hours.

As Dean Street (Route 44) is under the jurisdiction of the Massachusetts Department of Transportation Highway Division (MassDOT Highway Division) and the City of Taunton, MassDOT would coordinate construction and implementation of these intersection improvements with MassDOT Highway Division and the city at the appropriate time.

Stoughton Station Area Traffic Mitigation (Stoughton and Whittenton Alternatives)

Brock Street at Washington Street

A traffic signal would be warranted at the intersection of Brock Street at Washington Street under the Build Condition, and is recommended since the intersection would serve the primary station entrance. A capacity analysis for the signalized intersection was performed and the results were compared to the Build Condition (as an unsignalized intersection). The morning and evening peak hour under the signalized and unsignalized conditions are shown in Table 4.1-93. Signalizing the intersection upon relocation of the station would improve vehicle operations and mobility through the intersection.

Table 4.1-93 Brock Street/Kinsley Street at Washington Street–Build Condition

		Morning Peak Hour				Evening Peak Hour

1 demand in vehicles per hour
2 volume-to-capacity ratio, values over 1.0 indicate demand in excess of capacity.
3 average delay in seconds per vehicle
4 level of service for critical movement
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound; LT = left-turn; TH = through; RT = right-turn

Under traffic signal control, the calculated 95th percentile queue along Brock Street is 119 feet during the morning peak hour and 166 feet during the evening peak hour. This does not include additional queuing due to the active grade crossing. The available queue storage between the intersection of Brock Street at Washington Street and the tracks is approximately 130 feet. As traffic signal design progresses, queue detection and separate traffic signal heads at the grade crossing should be incorporated.

Wyman Street at Summer Street/Morton Street

The intersection of Summer Street/Wyman Street/Morton Street has atypical geometry and only the Summer Street approach is currently under traffic control. The intersection also includes two driveways that serve existing MBTA parking lots. Relocating Stoughton Station provides an opportunity to reconstruct this intersection. The following mitigation measures are recommended:

- Eliminate the Morton Square MBTA driveway and parking area;
- Close the Trackside Plaza South driveway; and
- Realign Morton Street and install a stop sign.

Two measures to mitigate impacts at the Brock St. grade crossing are recommended:

- The proposed traffic signal design plans should consider the effects of incorporating gate operations and restricting movements from Washington Street to Brock Street while the crossing gates are down. This would require changes in geometry along Washington Street to provide a separate northbound left-turn lane and southbound right-turn lane. The existing shoulders on Washington Street may be sufficiently wide to make these changes without the need for land acquisition.

- The traffic signal design plans should modify the existing driveways immediately east of the crossing to discourage motorists from using the parking lot as a way to avoid the traffic signal.

Easton Station Area Traffic Mitigation (Stoughton and Whittenton Alternatives)

Preliminary mitigation measures have been developed for locations that are projected to accommodate a substantial amount of project-related traffic and operate at or over capacity. The proposed mitigation for the Easton stations include signalization of the Union Street and Elm Street intersections with Route 138, pedestrian-related improvements in Easton Village area, and signal timing adjustments at the intersections of Route 138 and Roche Brothers Drive and Route 138 and Belmont Street. Table 4.1-94 presents a comparison of Build to Build with mitigation operations to illustrate the benefit of the proposed changes. Both Easton Stations are proposed as part of the Whittenton and Stoughton Alternatives.

Easton Village Traffic Mitigation (Stoughton and Whittenton Alternatives)

Due to the historic nature of the Easton Village area, specifically the Rockery monument, structural improvements to provide additional capacity are infeasible. Pedestrian level improvements are proposed for the area near this village-style station.

Main Street at Center Street and Lincoln Street (Stoughton and Whittenton Alternatives)—Proposed improvements at this intersection involve construction of ADA/AAB-compliant pedestrian ramps, new crosswalk and pavement markings. A passively-activated flashing pedestrian crossing sign would be installed at the Main Street crosswalk. This sign, activated when a pedestrian entered a detection zone at the pedestrian ramps of the crossing, would highlight the location as an active pedestrian crossing to approaching motorists.

Table 4.1-94 Easton Intersection Capacity Analysis–2030 Build with Mitigation Conditions vs. 2030 Build Conditions (Stoughton and Whittenton Alternatives)

Easton Village Station								
Route 138 at Belmont Street (Rt. 123)	E	0.87	53	D	F	0.93	58	E

Source: Synchro 7.0 Software; Build 763
1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
4 Unsignalized in the Build condition
L = Left-turn; T = Through; R = Right-turn; All = All movements
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Lincoln Street at Barrows Street (Stoughton and Whittenton Alternatives)—New crosswalk and stop line pavement markings would be installed at the Lincoln Street and Barrows Street intersection to improve visibility and safety. Wheelchair ramps would be assessed for ADA/AAB compliance and reconstructed if necessary.

Route 138 at Belmont Street (Route 123) (Stoughton and Whittenton Alternatives)—Measures have been proposed to mitigate traffic impacts associated with the full build-out of Queset Commons, a proposed mixed-use development in Easton Village. These measures include the reconfiguration of the site's driveway approach to an exclusive left turn lane with a combined through-right turn lane to allow overlapping left-turn phasing with the Belmont Street approach. It is recommended that this lane and phasing adjustment not be installed and that the approach remain in the initial mitigation configuration of a left turn-through lane and an exclusive right-turn lane with split phasing. With that configuration, the intersection is projected to operate at LOS E or better during both peak periods.

North Easton Station Area Traffic Mitigation (Stoughton and Whittenton Alternatives)

Route 138 at Roche Brothers Driveway (Stoughton and Whittenton Alternatives)—Minor traffic signal timing adjustments are proposed for this location. These adjustments are recommended to increase the crossing time for pedestrians crossing Route 138 and to facilitate exiting station traffic during the evening peak period. While these improvements are recommended for mobility reasons, they are not required to mitigate adverse project impacts. Levels of service during the morning and evening peak hours remain unchanged and at acceptable levels.

Route 138 at Union Street (Stoughton and Whittenton Alternatives)—This unsignalized intersection processes a high amount of traffic and operates at LOS F during the morning and evening peak hour with or without the project. To offset project related traffic at this intersection, a traffic signal would be installed at this location. The proposed signal would be designed to operate with three phases; the first phase serving as a lead phase for Route 138 southbound and the second phase for both northbound and

southbound Route 138. The third phase processes Union Street traffic. The new intersection would include concurrent pedestrian phases, wheelchair ramps and crosswalks. Pedestrian crossings would occur concurrently with these second and third phases. With the proposed improvement, the intersection of Route 138 and Union Street would operate at LOS A and LOS D during the morning and evening peak hour, respectively.

Signalization may be warranted at this intersection. Should these improvements be desired, MassDOT could contribute to the construction/implementation of these intersection improvements based on their fair share of the impacts to the intersection.

Route 138 at Elm Street (Stoughton and Whittenton Alternatives)—This unsignalized intersection processes a high amount of traffic and operates at LOS F during both the morning and evening peak hours with or without the proposed project. To offset project related traffic impacts at this intersection, a traffic signal would be installed. The proposed signal would be designed to operate with three phases; the first phase serving Route 138 northbound and southbound, the second phase serving Elm Street eastbound and the final phase serving Elm Street westbound. The new traffic signal would include concurrent pedestrian phases, wheelchair ramps and crosswalks. With the proposed improvement the intersection of Route 138 and Elm Street would operate at LOS C and LOS D during the morning and evening peak hour, respectively.

Signalization may be warranted at this intersection. Should these improvements be desired, MassDOT could contribute to the construction/implementation of these intersection improvements based on their fair share of the impacts to the intersection.

Route 138 at Main Street (Stoughton and Whittenton Alternatives)—This signalized intersection processes a high amount of traffic and would operate at LOS E during the morning peak hour and LOS F during evening peak hour without the project in place. With the proposed project, the intersection operates at LOS F during both peak hours. Traffic signal timing and phasing adjustments would be completed at this location to offset impacts from the proposed project. Specifically, a Main Street eastbound overlap right-turn phase would be added to the northbound/southbound Route 138 left-turn lead phase. The Main Street left-turn lead phase would be eliminated. Signal timing adjustments would be made to support the proposed changes. These proposed changes would allow the intersection of Route 138 at Main Street to operate at an acceptable LOS D during both the morning and evening peak hours.

Raynham Station Area Traffic Mitigation (Stoughton and Whittenton Alternatives)

The proposed mitigation for the Raynham Park Station includes signalization of the Raynham Park driveway, which would also be used as the station driveway, and signal timing adjustments at the intersection of Route 138 and Elm Street. Table 4.1-95 presents a comparison of Build to Build with mitigation operations to illustrate the benefit of the proposed changes. Raynham Park Station is proposed as part of the Whittenton and Stoughton Alternatives.

Table 4.1-95 Raynham Intersection Capacity Analysis–2030 Build with Mitigation vs. 2030 Build Conditions (Stoughton and Whittenton Alternatives)

	Weekday Morning Peak Hour				Weekday Evening Peak Hour			
	Build	Build with Mitigation			Build	Build with Mitigation		
Signalized Intersections	LOS[1]	V/C[2]	Delay[3]	LOS	LOS	V/C[2]	Delay[3]	LOS
Raynham Park Station								
Route 138 at Elm Street	B	0.79	21	C	B	0.83	22	C
Route 138 at Raynham Park Station Driveway[4]	F	0.56	12	B	F	0.63	14	B

Source: Synchro 7.0 Software; Build 763
1 level of service
2 volume-to-capacity ratio
3 average control delay for all vehicles, rounded to the nearest whole second, for signalized intersections
4 Unsignalized in the Build condition
L = Left-turn; T = Through; R = Right-turn
NB = Northbound; SB = Southbound; EB = Eastbound; WB = Westbound

Route 138 at Raynham Park Station (Stoughton and Whittenton Alternatives)

As part of the Raynham Park driveway signalization, the Robinson Street intersection on Route 138 would be shifted slightly north to align with the Raynham Park driveway, creating a four-way intersection. Route 138 would be widened at the intersection to accommodate an exclusive left-turn lane and two through lanes on the northbound approach and two general purpose lanes on the southbound approach. The new intersection would include pedestrian phases, wheelchair ramps and crosswalks. As shown in Table 4.1-95, the four-way signalized intersection would operate at LOE B in the morning and evening peak hours. These represent improved operations over the projected LOS F under Build conditions without mitigation.

As Route 138 is under the jurisdiction of MassDOT Highway Division, MassDOT would coordinate construction/implementation of these intersection improvements with MassDOT Highway Division at the appropriate time.

Route 138 at Elm Street (Stoughton and Whittenton Alternatives)

The signal timing at the Route 138 and Elm Street intersection would be adjusted to reduce delays on the Elm Street approaches and to provide adequate time for pedestrian crossings. The result is that all approaches would operate at acceptable levels of service but overall intersection operations would decline slightly from LOS B to LOS C.

4.1.6 Summary

The traffic analysis evaluated the traffic impacts of each of the commuter rail stations proposed as part of the Build Alternatives. Additionally, regional highway operations were evaluated to determine projected benefits of the regional transit enhancement associated with each of the alternatives. Traffic conditions in the vicinity of each station and along the regional highway network were analyzed for existing conditions and future 2030 conditions with and without the project. Mitigation would be implemented for roadways and intersections that would be most impacted by traffic associated with commuter rail stations associated with rail alternatives. In cases where Build Alternatives-related traffic would result in a degradation of operating conditions when compared to the No-Build Alternative,

mitigation measures were evaluated and would be implemented to address these impacts. Table 4.1-96 presents the recommended traffic mitigation for the project summarized by alternatives and stations.

Table 4.1-96 Recommended Traffic Mitigation Summary

Station	Intersection/Roadway	Mitigation
Stoughton and Whittenton Alternatives		
Fall River Depot Station	North Main Street at President Avenue	Widen North Main Street to provide an exclusive northbound and southbound left-turn lane Modify traffic signal phasing to provide a westbound lead phase and exclusive pedestrian phase
	President Avenue at N. Davol Street	Pedestrian timing improvements
Battleship Cove Station	Broadway at Central Street	Crosswalk and pedestrian ramp improvements
	Broadway at Anawan Street	Crosswalk and pedestrian ramp improvements
Freetown Station	South Main Street	Construction of approx. 1,600 feet of sidewalk along the eastern side of South Main Street
	South Main Street at Narrows Road	Crosswalk and pedestrian ramp improvements
	South Main Street at Copicut Street	Crosswalk and pedestrian ramp improvements
Whale’s Tooth Station	Acushnet Avenue at Hillman Street	Crosswalk and pedestrian ramp improvements
	Acushnet Avenue	Construction of approx. 300 feet of sidewalk along eastern side of Acushnet Avenue
	Mill Street at Pleasant Street and Kempton Street	Revised signal timing, including longer pedestrian timings
	Coggeshall Street at North Front Street	Install traffic signal
	Coggeshall Street at Purchase Street	Install traffic signal
King’s Highway Station	King’s Highway	Install signal interconnect infrastructure between Mount Pleasant Street and Church Street
	Mount Pleasant Street at Jones Road/King’s Highway	Revised signal phasing and timings
	King’s Highway at Shaw’s Drive	Signal equipment, phasing and timing improvements to provide concurrent pedestrian crossing
	King’s Highway at Stop & Shop Drive	Grade crossing signal pre-emption Reconfigure Stop & Shop Drive to accommodate diverted Tarkiln Hill Road traffic
King’s Highway Station	Tarkiln Hill Road at Church Street	Grade crossing signal pre-emption Revised signal timing , including longer pedestrian timings

Station	Intersection/Roadway	Mitigation
Taunton Depot Station	Route 140 at Hart Street	Revised signal timing
	Taunton Depot Drive	Construction of sidewalk along the northern side of the Target Plaza parking lot to station area
Whittenton Alternative		
Dana Street Station	Tremont Street at Granite Street	Restripe existing crosswalks using high visibility materials
	Washington Street at Tremont Street	Review existing grade crossing pre-emption timing Restripe Washington Street for an exclusive right-turn and combined left/thru lanes Revised signal timing , including longer pedestrian timings
	General	Prepare traffic calming mitigation plan.
Stoughton Alternative		
Taunton Station	Broadway and Washington Street	Revised signal timing
	Dean Street at Longmeadow Street	Restripe Longmeadow Street to provide two southbound lanes Revised signal timing, including longer pedestrian timings
	Dean Street at Prospect Street	Install pavement marking and signage improvements
	Dean Street at Arlington Street	Reconstruct traffic signal system based on new adjacent grade crossing equipment Widen Arlington Street to provide two southbound lanes
	Arlington Street at School Street	Convert to all-way stop
Stoughton and Whittenton Alternatives		
Raynham Park Station	Route 138 at Elm St.	Revised signal timing, including longer pedestrian timings
	Route 138 at Dog Track/Station Driveway	Re-align Robinson Street to create 4-way intersection Widening of Route 138 to provide two lanes northbound and southbound Install traffic signal
Easton Village Station	Route 138 at Belmont Street	Revised signal phasing and timings
	Main Street at Center Street/Lincoln Street	Install pavement marking and signage improvements
	Lincoln Street at Barrows Street	Install pavement marking and signage improvements
North Easton Station	Route 138 at Roche Bros. Way	Revised signal timings
	Route 138 at Main St.	Revised signal timing, including longer pedestrian timings
	Route 138 at Elm St.	Widening of Route 138 to provide two lanes northbound and southbound

Station	Intersection/Roadway	Mitigation
		Install traffic signal
	Route 138 at Union St.	Widening of Route 138 to provide two lanes northbound and southbound
		Install traffic signal
Stoughton Station	Brock Street at Washington Street	Install traffic signal
	Wyman Street at Summer Street/Morton Street	Reconstruct intersection (eliminating driveways, realign Morton St. and install stop sign).

The impact analysis examined the traffic and safety impacts associated with the public grade crossings that would be in service along each of the Build Alternatives, with each crossing's recommended treatment (grade separation, closure, or at-grade crossing). Traffic conditions at existing grade crossings were evaluated, as increased train frequency at these grade crossings could affect traffic flows and roadway capacity on either side of each grade crossing. The grade crossing incident analysis summarized the probability of an incident occurring over the span of a year at each of the proposed at-grade crossings along each of the Build Alternatives as well as the probability of an incident occurring at each of the intersections that currently contain rail operations.

Based on the traffic and safety analysis conducted, general recommendations for traffic and safety improvements were made for all Build Alternatives. These general improvements include measures to optimize safety at the proposed at-grade crossings, including design features, signage, site conditions, signals and operations, vital logic and automatic highway crossing warning systems. Additionally, site-specific mitigation measures that could be undertaken by MassDOT to offset these impacts were presented by municipality and street. These specific improvements range from minor to major construction. Where structural changes to the roadway and traffic control devices are proposed, mitigation measures aim to improve traffic flow with minimal impacts to adjacent land uses and at reasonable cost. Table 4.1-97 presents the recommended at-grade crossing safety improvements for the Stoughton and Whittenton Alternatives, respectively, summarized by municipality and street.

Table 4.1-97 Recommended Grade Crossings Mitigation Summary

Town/City	Street	Recommended At-Grade Crossing Safety Improvements
STOUGHTON LINE		
Canton	Washington Street	Install a traffic signal pre-emption system at two intersections in proximity of the crossing
	Pine Street	Relocate existing driveway to the north
	Will Drive	General improvements
Stoughton	Central Street	Relocate existing driveway to the west
		Coordinate crossing operation with fire station located 400 feet west
		Extend sidewalk through the crossing
		Install crosswalk across the Central Street eastbound approach to the crossing
	Simpson Street	General improvements
	School Street	Modify alignment at Cushing Street
	Porter Street (Route 27)	General improvements
	Wyman Street	Reconfigure parking lot and driveway

Town/City	Street	Recommended At-Grade Crossing Safety Improvements
	Brock Street	Investigate installation of a traffic signal with pre-emption system at nearby intersection Reconfigure driveway to the east and relocate driveway to the west
	Plain Street	Investigate installation of a traffic signal with pre-emption system at nearby intersection Relocate driveways to the east
	Morton Street	Close Morton Street Construct frontage road to Totham Farm Road
Easton	Elm Street	Relocate driveway to the east
	Oliver Street	Relocate driveways to the northwest Relocate children's play area Extend sidewalk through crossing
	Gary Lane	Install gates and locks
	Short Street	General improvements
	Depot Street (Route 123)	Reconfigure driveway to the west
	Purchase Street	General improvements
	Prospect Street	General improvements
	Foundry Street (Route 106)	General improvements
Raynham	Race Track Crossing	General improvements
	Elm Street	General improvements
	Carver Street	Reconstruct culvert
	Broadway (Route 138)	At-grade separation
	Britton Street	General improvements
	King Philip Street	Relocate driveways
	East Britannia Street	General improvements
Taunton	Longmeadow Road	Reconfigure or close driveways
	Dean Street (Route 44)	Reconstruct Dean Street/Arlington Street traffic signal system Install traffic pre-emption phasing at Dean Street/Arlington Street
NEW BEDFORD MAIN LINE		
	Ingell Street	Close driveway to the west
	Hart Street	General improvements
Berkley	Cotley Street	General improvements
	Padelford Street	General improvements
	Myricks Street (Route 79)	General improvements
Lakeville	Malbone Street	General improvements
Freetown	Chace Road	Reconfigure or close driveway to the west
	Braley Road	General improvements
	East Chipaway Road	General improvements
New Bedford	Samuel Barnet Road	General improvements
	Pig Farm Road	General improvements

Town/City	Street	Recommended At-Grade Crossing Safety Improvements
	Tarkiln Hill Road	Close Tarkiln Hill Road and reroute traffic through Stop & Shop driveway Signal pre-emption at King's Highway / Stop & Shop driveway Signal pre-emption at Tarkiln Hill Road / Church Street At-grade crossing pre-signals
	Nash Road	Signal pre-emption at Church Street / Nash Road At-grade crossing pre-signals
FALL RIVER SECONDARY		
Berkley	Mill Street	Close crossing
	Adams Lane	Close crossing
Freetown	Beachwood Road	Close crossing
	Richmond Road/Route 79 (North)	General Improvements
	Richmond Road/Route 79 (South)	Reconfigure driveway to the west
	Forge Road (North)	Close Forge Road
	Forge Road (South)	General improvements
	Elm Street	General improvements
	High Street	General improvements
	Copicut Road	General improvements
	Brightman Lumber	General improvements
ATTLEBORO SECONDARY (Whittenton Alternatives Only)		
Taunton	Tremont Street	Reconfigure driveway to the north
	Oak Street	Optimize existing pre-emption at Oak Street / Tremont Street
	Porter Street	Reconfigure driveway to the east
	Cohannet Street	Reconfigure or close driveways adjacent to the tracks
	Winthrop Street	Additional advance RR warning signs
	Somerset Avenue	Investigate installation of a traffic signal with pre-emption system at nearby intersection
	Weir Street	Close McSoley Street Close and reconstruct driveway to the west Close and reconstruct driveway to the east

The MBTA Safety Department also seeks to minimize incidents within the system through grade crossing safety policies and programs, such as routine safety audits and the Safety and Operations Rules and Compliance Program.

4.2 LAND USE AND ZONING

4.2.1 Introduction

This chapter characterizes land uses and zoning in the study area and assesses the impacts of the alternatives on land use. Section 4.2.1 defines land use and zoning, and provides the regulatory context for studying this resource. Section 4.2.2 identifies the South Coast Rail project study area, summarizes regional land use conditions, and describes existing conditions (relative to land use and zoning) within the study area. Section 4.2.3 discusses the effects to land use that may result from implementing each of the proposed South Coast Rail project alternatives (including railroad alignments, stations and layover facilities). Any parcels that would be acquired for construction or reconstruction for any component of each of the alternatives are also identified in Section 4.2.3. The parcels, or portions of parcels, would be acquired by the state and by definition become publicly owned. Existing land uses would be converted to transportation/utilities uses.

The Secretary of the Executive Office of Energy and Environmental Affairs (EEA)[1] issued a Certificate on the ENF on April 3, 2009. The certificate includes a number of requirements defining the scope of the Environmental Impact Report (EIR). However, no specific requirements for evaluation of impacts to land uses or to the social and economic environment are included in the Certificate.[2]

4.2.1.1 Resource Definition

Land use refers to the types of activities occurring on a parcel, as determined by aerial photograph interpretation, local zoning designation, and field observation. Common land uses in the South Coast region include residential, commercial, recreational, and undeveloped land. Zoning is a system of land-use regulation that prescribes the use to which land may be put, based upon local (municipal) jurisdiction. Zoning is defined by the Commonwealth of Massachusetts as "ordinances and by-laws, adopted by cities and towns to regulate the use of land, buildings and structures to the full extent of the independent constitutional powers of cities and towns to protect the health, safety and general welfare of their present and future inhabitants."[3]

4.2.1.2 Regulatory Context

There are no state or federal regulations applicable to the evaluation of land use. The CEQ NEPA regulations do require that an Environmental Impact Statement evaluate a proposed action's impact on "urban quality, historic and cultural resources, and the design of the built environment," including the reuse and conservation potential of various alternatives and mitigation measures.[4] The Corps' public interest review includes land use as a public interest factor (33 C.F.R. § 320.4(a)).

4.2.1.3 Methodology

The following describe how potential direct effects of the South Coast Rail project to land use were evaluated. Potential indirect land use changes (such as changes in growth patterns) associated with the alternatives are addressed separately in Chapter 5, *Indirect and Cumulative Impacts*.

---

[1] Formerly, the Executive Office of Environmental Affairs.

[2] Certificate of the Secretary of Energy and Environmental Affairs on the Environmental Notification Form. South Coast Rail Project. April 3, 2009.

[3] Commonwealth of Massachusetts. *MGL c. 40A Zoning, s. 1A Definitions, "Zoning."*

[4] Council on Environmental Quality. 2009. *Code of Federal Regulations (CFR), Title 40: Protection of the Environment, Part 1502-Environmental Impact Statement, Section 16(g) Environmental Consequences (40 CFR 1502.16(g)).*

Potential direct effects to land use were evaluated by first reviewing areas where construction would be required for each of the alternative alignments outside of the existing rights-of-way. For the purposes of this evaluation, “construction” is defined as upgrading existing rail lines, reconstructing rail lines along out-of-service railroad alignments, constructing entirely new railroads, replacing existing railroad bridges and culverts, constructing new permanent or temporary railroad bridges, reconfiguring at-grade road/railroad crossings, constructing new grade-separated road/railroad crossings, constructing or reconstructing train or bus stations, and constructing layover facilities.

The analysis was conducted to determine if land acquisition would be required to accommodate construction, and identify the ownership and use of parcels designated for acquisition. “Land acquisition” is defined as taking a greater than 500-square-foot portion, or a sliver greater than 10 feet wide, of any parcel outside of the existing rights-of-way to accommodate permanent construction impacts, and is based on preliminary engineering plans. Final engineering plans may show an increase or decrease of the actual area of acquisition required, land use would be unlikely to change as a result of parcel acquisition below these thresholds, and social and economic effects would be negligible. Temporary construction impacts outside of the existing rights-of-way would not require land acquisition and are therefore not considered in this evaluation. Narrow slivers of parcels or temporary construction easements were not considered in the evaluation of land acquisition, given the scale and accuracy of the preliminary engineering plans. Aerial photographs and land use maps were examined in reference to preliminary engineering plans to identify encroachments onto adjacent parcels.

The parcel ownership and land usage were identified using multiple sources, including aerial photography, field visits, MassGIS (2005 data) and municipal mapping (obtained in 2008), information provided by Southeastern Regional Planning and Economic Development District (SRPEDD), and the *South Coast Rail Economic Development and Land Use Corridor Plan* (the Corridor Plan).[5] The general land use categories depicted on the maps reflect land use designations identified by the specific source(s) used or were aggregated for map legibility purposes. For example, the generalized land use category “open water” was based on the 2005 Land Use layer provided by MassGIS, and is also included in the DEP wetlands layer. Zoning designations were obtained from the respective communities within the study area. Because the data used for this analysis were derived from several sources with differing definitions of land use and zoning designations, these categories have been generalized in this evaluation for a suitable comparison. Four general categories of privately owned parcel land uses and zoning designations were established: residential, commercial, industrial, and undeveloped. The “industrial” category encompasses industrial businesses as well as transportation corridors and sites such as sand and gravel mining operations, the “undeveloped” category encompasses natural open space, parks and recreation sites, and agricultural lands and the “commercial” category includes institutional uses such as schools and places of worship. Where appropriate for the purposes of this evaluation, land use or zoning identified as transportation/utilities by one or more of the above sources is specifically noted as such rather than generalized as industrial.

MassGIS data supplemented by municipal data and field visits were used to characterize and map land uses and zoning at each proposed station site, within 0.5 mile radius of each proposed station site, and within 0.5 mile of each section of the alternative corridors that is not currently in transportation use.[6] These distances were selected as the maximum extent of resource areas that could potentially be affected by the proposed project.

[5] EOT. 2009. South Coast Rail Economic Development and Land Use Corridor Plan. Commonwealth of Massachusetts, Executive Office of Transportation and Public Works, and Executive Office of Housing and Economic Development. Prepared by Goody Clancy: Boston.

[6] Zoning is described on or near station sites and not in the vicinity of alternative alignments.

Appendix 4.2-A provides detailed information on the generalized land use mapping generated using MassGIS data.

4.2.2 Existing Conditions

The following describes the existing land uses and zoning in the South Coast communities along a 0.5-mile wide corridor encompassing each alternative alignment and within a 0.5-mile radius of each proposed station location. The discussion provides a regional overview of existing land use and zoning followed by a discussion of exiting land uses found in the study corridor.

4.2.2.1 Regional Overview of Existing Conditions

Land Use Study Area

The communities that would be served or that could be directly impacted by the Stoughton and/or Whittenton Alternatives are listed in Table 4.2-1. The alternative railroad alignments pass through or near these communities, and new station sites are within or near each. Land use and zoning within each of these communities, relative to the alternative alignments and station sites, is discussed in Section 4.2.2.2.

Southeastern Massachusetts, an area which includes the South Coast region, has been the fastest growing region in the Commonwealth in terms of both population and housing units. As a result, the region has been subject to rapid land development. However, cities such as Fall River and New Bedford have seen their populations decline.

Table 4.2-1 also illustrates the difference in the amount of developable land of the South Coast communities.[7] Based on 2000 MassGIS data, the majority of the land within the South Coast area remains undeveloped (65 percent) and residential (19 percent). The remaining land is agricultural (9 percent), commercial/industrial (3 percent), transportation/utility (2 percent), and recreational (2 percent).

The following sections describe the character of the typical development patterns in the South Coast communities: sparsely developed (suburban/semi-rural) and densely developed (urban).

Sparsely Developed Areas

Suburban development patterns exist in those communities closest to Boston and with good transportation connections to the Boston metropolitan area, such as Canton, Stoughton, and Easton. These communities are served by I-95/Route 128 and the existing commuter rail lines. Semi-rural communities along I-495, including Raynham and Taunton, remain predominantly rural although suburban development has been increasing. The coastal communities south of I-495 (including Freetown) are areas of seasonal residents and visitors, with residential and agricultural land uses. Residential uses within these communities are typically separated from commercial and industrial areas.

Lower-density, single-family residential developments dominate these suburban and semi-rural communities. The majority of residential land use exists along local road networks. Multi-family residential use is generally not common in these areas. However, some proposed station sites close to

[7] For purposes of this analysis, developable land is defined as large parcels of land that could be developed into new subdivisions or new commercial/industrial properties or could be placed into permanent or limited open space protection.

town centers or villages (such as in Easton and Taunton) are in areas that have somewhat higher-density housing, such as two- and three-family properties and small lots.

Commercial and industrial land uses within the region generally follow a sprawling pattern. Although commercial and industrial land uses are in city and town centers, many are also found in non-urban settings along major interstate and state highways, and at interstate exits and interchanges. Many of the largest identified commercial and industrial land use areas are found in non-urban settings away from city and town centers.

Table 4.2-1 Land Use Study Area Communities: Developable Areas

Town	Percent Developable
Canton	23.3
Stoughton	18.0
Easton	40.8
Taunton	31.5
Raynham	49.8
Berkley	N/A
Lakeville	34.4
Freetown	51.5
Fall River	33.1
New Bedford	22.4

Source: MassGIS (2000)
N/A Not Available

Densely Developed Areas

The largest cities in the region are New Bedford and Fall River, both former industrial centers, each with a population just under 100,000. Higher-density, multi-family land uses are present in these cities.

New Bedford has a long history of maritime activity, first rising to prominence in the late eighteenth century as one of the most important cities in the whaling industry. This role lasted through the nineteenth century until the decline of whale populations and the rise of petroleum products caused the industry to collapse. New Bedford remained an important textile manufacturing city into the early twentieth century, until those factories declined and relocated to regions with cheaper labor. Though diminished, manufacturing remains an important economic activity. Maritime commerce is still extremely important, as New Bedford is one of the hubs of the New England fishing industry, consistently rating as one of the busiest fishing ports in the country.

Fall River, built on a large bluff above the Taunton River, climbed to importance during the middle nineteenth century due to the availability of water power on the Quequechan River where it descends the bluff. At its height, Fall River's textile industry was second in the country only to that of Manchester, New Hampshire. Like New Bedford, Fall River suffered greatly with the decline of manufacturing in New England.

In terms of population, the third largest community in the region is Taunton, north of Fall River at the head of the Taunton River estuary. Taunton was historically known as a major city in the silversmith and shipbuilding industries. Manufacturing and electronics remain important industries.

Undeveloped Areas

The region also encompasses large expanses of forested land, as well as agricultural and recreational areas. The recreation and park areas, protected public open space and Areas of Critical Environmental Concern (ACECs) are described in Chapter 4.10, *Protected Open Space and Areas of Critical Environmental Concern*, and the agricultural lands are described in Chapter 4.11, *Farmland Soils*.

Regional and Municipal Land Use Plans

SRPEDD, the regional planning agency serving 27 cities and towns in Southeastern Massachusetts, has taken an active role in conducting studies and analyses for some of the affected communities. In conjunction with the South Coast Rail project and the Southeastern Massachusetts Commuter Rail Task Force, SRPEDD has been working with the cities and towns of the region to identify those areas that are priorities for development and priorities for land protection efforts. SRPEDD has worked with municipal officials and citizens to locate and designate Priority Development Areas (PDAs) and Priority Protection Areas (PPAs) within each community. Mapping and final PDA/PPA reports are complete for all 27 communities in the South Coast Region.[8]

4.2.2.2 Existing Conditions within the Study Corridor

Southern Triangle (Common to All Build Alternatives)

The land uses along the New Bedford Main Line (Figures 4.2-1a-d) are primarily low-density residential and undeveloped in Berkley, and forested and undeveloped land with some low-density residential through Lakeville, Freetown, and northern New Bedford. In southern New Bedford, which is urban in character, the land uses are widely mixed and dense, including high-density residential, commercial, industrial, and some institutional uses. A portion of the New Bedford Main Line runs through Taunton, including the downtown area, adjacent to residential, recreational, commercial, and industrial uses. Additional land uses that occur less frequently along the alignment include mixed use, commercial, agriculture, and municipal- or state-owned land. The most developed area along the New Bedford Main Line is in New Bedford, followed by Taunton and Berkley.

The land uses along the Fall River Secondary (Figures 4.2-2a-c) are predominantly forested, undeveloped, and low-density residential with some industrial parcels through Freetown, and moderate-density residential, undeveloped and recreational through northern Fall River. Once the Fall River Secondary enters downtown Fall River, the land uses are more mixed, including higher-density residential, industrial, and commercial properties. This is the most developed area along the Fall River Secondary. Portions of the corridor through Fall River abut the Taunton River waterfront.

Stoughton Alternative

Land use adjacent to the Stoughton Line (Figures 4.2-3a-e) is predominantly moderate-density residential through Canton, Stoughton, and Easton. The alignment passes through a large industrial area at the Canton/Stoughton boundary and the commercial center of Stoughton. Additional land uses along

[8] Southeastern Regional Planning and Economic Development District (SRPEDD) website. http://www.srpedd.org/PPA-PDA.asp. Accessed on January 2, 2013.

the Stoughton Line in these towns include agricultural, municipal-owned, and forested land (particularly in southern Stoughton and northern Easton). Easton is largely low-density residential and undeveloped land, although high-density urban development is present in downtown Easton. The railroad also passes adjacent to a large recreational parcel (golf courses) and the Southeastern Regional Vocational Technical School. In southern Easton, the alignment crosses through the Hockomock Swamp. In this area, the Hockomock Swamp is largely undeveloped with the exception of electric power transmission infrastructure extending roughly southeast to northwest across the alignment. In Raynham, the Stoughton Line passes through a greater mix of uses, such as commercial, including the former Raynham Greyhound Park, low-density residential, , as well as undeveloped area, including Pine Swamp. The land uses adjacent to the Stoughton Line through Taunton are primarily moderate- to high-density residential, supplemented by a mix of undeveloped, commercial and industrial uses.

Whittenton Alternative

Land uses within 0.5 mile of the Whittenton Alternative are the same as described above for the Southern Triangle and Stoughton Alternative, with the exception of the Whittenton Branch alignment and the Attleboro Secondary segment through downtown Taunton (Figures 4.2-4a-b). In these areas, land uses are predominantly moderate-density residential interspersed with industrial (including a gravel pit), commercial and undeveloped land. As the Whittenton Branch alignment and associated Attleboro Secondary segment pass through downtown Taunton, the nearby land uses are a mix of dense commercial, institutional, and industrial parcels.

Stations

Southern Triangle Stations (Common to All Build Alternatives)

The Southern Triangle includes two rail alignments south of Cotley Junction and the six Southern Triangle stations are therefore common to all build alternatives.

King's Highway Station Site—The King's Highway Station site, in northern New Bedford along the New Bedford Main Line on King's Highway east of Route 140, would serve all of the build alternatives (Figure 4.2-5). The station would occupy part of an approximately 55-acre site that is now a shopping plaza. The traditional strip-style shopping center contains various commercial businesses, including McDonald's, Ocean State Job Lot, Rent-A-Center, H&R Block, Family Dollar, Fashion Bug, Fashion Nails and others. A parking area occupies approximately half of the site. Adjacent uses include two smaller shopping centers and associated parking; one west and south, and one north across King's Highway.

East of the rail alignment, beyond the industrial and commercial uses, is a large residential neighborhood. This moderate-density residential neighborhood contains mostly single-family properties and some two- and three-family properties. West of Route 140 there is another residential neighborhood as well as the New Bedford Regional Airport, additional commercial and industrial uses, and a cemetery.

Zoning at the King's Highway Station site is general industrial (Figure 4.2-6). Zoning near this site is high-density single-family residential and low-density multi-family (R5), mixed use, and general and light industrial.

Whale's Tooth Station Site—The Whale's Tooth Station, at the Whale's Tooth parking lot in New Bedford along the New Bedford Main Line, would serve all of the build alternatives (Figure 4.2-7). This

14-acre site on the New Bedford waterfront was identified as the preferred site in the 2002 Final EIR. The city of New Bedford has constructed a parking lot on the site in anticipation of the rail project. This site is approximately 0.5 mile north of the proposed State Pier Station site. The site is within 0.25 mile of the waterfront and in proximity to downtown New Bedford and the Hicks-Logan redevelopment area.

The Whale's Tooth Station site is currently a municipal parcel, and adjacent parcels are mainly large-scale, maritime-related, industrial uses and undeveloped land to the east, industrial to the south, and commercial and moderate- to high-density residential uses to the west. Within the 0.5-mile radius of the Whales' Tooth Station site, Route 18 serves as a significant barrier between the industrial uses along the mixed-use neighborhood west of Route 18. North of the site, the former Wamsutta Mill building is in the process of being converted into residential units (this land use is not depicted in Figure 4.2-7, which is based on 2005 data). Wamsutta Mills is the first conversion to residential use to occur east of Route 18 within 0.5 mile of the Whale's Tooth Station site.

Zoning at the Whale's Tooth Station is general industrial (Figure 4.2-6). Zoning near this site is high-density single-family residential and low-density multi-family (R5), mixed use, and general and light industrial.

Freetown Station Site—The Freetown Station site, on South Main Street along the Fall River Secondary, would serve all of the build alternatives (Figure 4.2-8). The approximately 18-acre site currently includes both undeveloped and industrial land uses. The developed portion is occupied by a self-storage business. The surrounding land is mainly forested, with some residential and industrial uses. South Main Street is a small road but accommodates significant traffic due to the industrial uses in the area.

Generally, the 0.25-mile radius around the Freetown Station site contains few residential properties. Low-density residential uses are immediately across South Main Street and to the north, which would be sensitive noise or vibration receptors. The low-density residential neighborhood becomes more prominent 0.5 mile north of the site. Between 1 and 2 miles south of the site, at the exit from Route 24, there is a large residential population in apartment and condominium properties.

The Freetown Station site is in proximity to two industrial parks—the proposed Fall River Executive Park and the Riverfront Park—that are projected to provide thousands of jobs.[9] There are industrial parcels north and south of the site, including the Stop & Shop Distribution Center.

Zoning at the Freetown Station site is mixed use (Figure 4.2-9). Zoning near this site is light industrial and mixed use.

Fall River Depot Site—The Fall River Depot Station, 1 mile north of downtown Fall River along the Fall River Secondary at Route 79 and Davol Street, would serve all of the build alternatives (Figure 4.2-10). The proposed station would be on a site bounded by Pearce Street to the north, the existing railroad line to the east, Braylies Street to the south, and North Davol Street to the west. A portion of the site was last in industrial use but is now vacant; other portions include commercial uses. A historic train station, now demolished, was on the site. The northern portion of the site was a foundry, and the Old Colony Depot was occupied by a steel company. The proposed Battleship Cove Station site is approximately 1 mile south of the Fall River Depot Station site.

[9] Massachusetts Executive Office of Transportation and Public Works and Massachusetts Bay Transit Authority, Station Siting Report EOT's Final Recommendations, October 10, 2008.

The adjacent parcels are all commercial; some are vacant. Within the 0.5-mile radius of the Fall River Depot Station site is a dense residential neighborhood to the east, an older shopping plaza to the north, and a redeveloping waterfront across Route 79 to the west. Residential properties immediately east of the railroad line appear to be new or recently upgraded, reflecting ongoing improvements to this neighborhood.

The developing waterfront along Route 79 consists of a mix of uses, including industrial, residential, commercial, municipal, and recreational/open space. The Fall River Depot Station site is somewhat isolated from the waterfront. Connectivity between the site and the waterfront is currently limited to an underpass at President Avenue (one block north of the site).

Zoning at the Fall River Depot Station site is general industrial (Figure 4.2-11). Zoning near this site includes high-density, single-family residential and low- to moderate-density multi-family (R5 and MM), general business, and general and light industrial.

Battleship Cove Station Site—The Battleship Cove Station, an approximately 2.2-acre site along the Fall River Secondary on the Fall River waterfront at the Ponta Delgada Plaza, would serve all of the build alternatives (Figure 4.2-12). The site is a triangular-shaped parcel adjacent to the monument, currently owned by the city of Fall River, between the existing railroad and Water Street. Portions of the site occupy what used to be part of Crab Pond that was filled in ca. 1982; this activity was authorized by Department of the Army Permit No. MA-FALL-80-161, issued by the Corps of Engineers on June 2, 1980. The Fall River Depot Station site (described above) is approximately 1 mile north of the Battleship Cove Station site.

The immediately adjacent parcels are mostly industrial, including a Federal Express Distribution Center and a converted mill building. Commercial and institutional land uses are beyond the industrial uses to the north and southwest. Other uses in the vicinity include a dense residential neighborhood to the east and municipal land to the south. The residential neighborhood contains scattered mixed-use and commercial properties, as well as a few institutions and religious uses.

The Battleship Cove Station site is on the waterfront, close to downtown Fall River, near the Fall River Heritage Park and other tourist attractions such as the Heritage State Park, the Old Colony and Fall River Rail Museum, and the Marine Museum. The waterfront area is characterized by old manufacturing buildings and vacant land that the City would like to redevelop.

Zoning at the Battleship Cove Station site is general industrial (Figure 4.2-11). Zoning near this site includes high-density, single-family residential and low- to moderate-density multi-family (R5 and MM), general business, and general and light industrial.

Taunton Depot Station Site—The Taunton Depot Station (formerly, East Taunton [North]) site is at the rear of Target Plaza off of Route 140 (Figure 4.2-13). The site is currently undeveloped, with half the site cleared and half forested. The 14-acre site is primarily surrounded by forest and undeveloped parcels to the north, west, and south. Target Plaza, east of the site, is a big-box retail site that contains a Target, Home Depot, and other stores. Beyond the railroad alignment to the west is a low-density residential neighborhood.

In addition to undeveloped land, the 0.5-mile radius surrounding this site predominantly consists of residential, agricultural, and commercial (primarily Target Plaza) uses. Residential uses along Route 140

are moderate-density, such as small apartment buildings and townhomes. Single-family residential uses are west of the site.

Zoning at the Taunton Depot Station site is moderate-density, single-family residential (Figure 4.2-14). Zoning near this site is predominantly moderate-density, single-family residential with some general industrial.

Stoughton Alternative Station Sites

In addition to the Southern Triangle, the Stoughton Alternatives would provide commuter rail service from South Station through Stoughton to Canton Junction and Weir Junction. The Stoughton Alternatives have five stations in addition to the Southern Triangle stations described above. This section discusses the land use and zoning at or near the proposed station sites for the Stoughton Alternative.

Stoughton Station Site—As described in Chapter 3, *Alternatives*, the existing Stoughton Station would be relocated to accommodate a second track. The station would be shifted from its present location between Porter and Wyman streets to a new location south of the Wyman Street at-grade crossing (Figures 4.2-3a and 4.2-3b). The proposed station site is privately owned and is currently occupied by commercial and industrial uses, including warehouses/office space used by the Alpha Chemical Company and property of the Murphy Coal Company (fuel storage and materials handling yard, parking lot, and vehicle repair garage).

The Stoughton Station site is surrounded by developed land in the center of Stoughton. Land uses within 0.5 mile of the relocated Stoughton Station include a mix of industrial, commercial, and residential, along with community facilities such as the Stoughton Public Library.

The Stoughton Station site is located within a general industrial zoning district (Figure 4.2-3a). Surrounding zoning districts include central business and general business districts to the north in the center of Stoughton, a general business district to the east (between the railroad tracks and Washington Street) and several single-family residential zoning districts.

North Easton Station Site—The proposed location for the North Easton Station is off Route 138 near the Easton-Stoughton municipal border (Figure 4.2-15). The site is largely hidden from Route 138, behind an approximately 10-acre retail plaza that is anchored by the Roche Brothers Supermarket. The North Easton Station site is currently undeveloped. New medical buildings have recently been constructed nearby and two additional buildings are planned. In addition to the commercial and offices uses at the shopping plaza, the site is surrounded by forest and undeveloped land.

Residential, forested, and institutional uses are within a 0.5-mile radius of the North Easton Station site. South of the site is a sparsely-settled suburban residential area interspersed with commercial uses. The area north of the site along Route 138 is characterized by a mix of apartments and automobile-oriented commercial uses.

The residential uses near the North Easton Station site are moderate- to low-density characterized by single-family homes south of the site and small apartment buildings west and north of the site. Many of the homes in this area appear new and were most likely built within the last 30 years.

Zoning at the North Easton Station site is general business (Figure 4.2-16). Zoning near this site is almost entirely low-density single-family residential with some general business zoned land in both Stoughton and Easton.

Easton Village Station Site—The Easton Village Station site is south of the historic H.H. Richardson train station (Figure 4.2-17). This site is within Easton Village (downtown Easton). Adjacent land uses are commercial, institutional, undeveloped and industrial. A new 113-unit residential condominium complex is under construction directly west of the historic station. Specifically, these land uses include a restored mill complex that currently contains offices,[10] the former train station (now occupied by the Easton Historical Society), and a municipal park adjacent to Shovel Shop Pond to the east. Residences are located within 0.25 mile of the site.

Within a 0.5-mile radius of the Easton Village Station site is predominantly moderate-density residential development typical of a New England town center. These residences are closely set and generally greater than 50 years old. Other uses in the vicinity include commercial, municipal, and institutional properties, as well as a state-owned property and places of worship/religious institutions. Other properties include a town-owned parking lot, an H.H. Richardson-designed library, and a vacant mill building.

South of the Easton Village Station site, Main Street is characterized by an approximately two-block strip of small, two-, and three-story commercial properties. Many former single-family homes along Main Street have been converted to commercial uses and contain low-intensity professional services such as a doctor's office or realtor. Some of these properties are residential with a home office.

Zoning at the Easton Village Station site is general industrial (Figure 4.2-16). Zoning near this site is almost entirely low-density single-family residential, with small areas of light industrial and general business.

Raynham Park Station Site—The Raynham Park Station is at the former site of the Raynham-Taunton Greyhound Park in Raynham (Figure 4.2-18). The station would be on a portion of this 80-acre site. Although noted as recreational in Figure 4.2-18 due to the race track on the larger site, the specific station site is currently a paved roadway and parking lot, and portions of an industrial operation. The site is currently used as simulcast/off-track betting facility.

The land uses adjacent to the Raynham Park Station site are a mix of forest, recreation, industry, and commercial. The former greyhound park property occupies much of the land in the 0.5-mile radius around the site. North of the site, Route 138 is primarily forested. South of the site, Route 138 has low-density residential uses and an agricultural parcel. Multi-family residential properties are more than 1 mile to the north.

Zoning at the Raynham Park Station site is general industrial (Figure 4.2-19). Zoning near this site is almost entirely general industrial, with some general business and low-density, single-family residential.

Taunton Station (Dean Street) Site—The Taunton Station is at the Dean Street site (Figure 4.2-20). The site is approximately 8 acres and is near Route 44 just north of the historic train station. Downtown Taunton is approximately 0.75 to 1 mile from the site. The site is bounded by Arlington Street, Belmont Street, and the existing railroad and is primarily vacant. Currently, parcels comprising the site are owned

[10] This parcel is noted as institutional on Figure 4.2-16 due to the ownership.

by the city and by private entities. The city-owned parcel was a former rubber plant that burned. The city of Taunton has invested in remediating this Brownfield site in anticipation of a future train station. The two private parcels are:

- A former granite storage facility that partially burned in March 2008. One building and a garage remain on this parcel.

- An undeveloped lot used for storage for a nearby auto-body use on Arlington Street. This parcel is currently vacant and contains debris.

Adjacent parcels are forest to the north and east, residential to the west, and commercial to the south. Industrial, institutional (nursing home), and recreational/municipal (ball fields) properties interspersed with forest are east of the railroad right-of-way, and accessed from Longmeadow Road or Dean Street.

Moderate-density residential is the predominant land use within 0.5 mile of the Taunton Station site, particularly north and west. A few commercial, industrial, religious, and undeveloped parcels are scattered throughout the vicinity. The Taunton River runs south of the site under Route 44. South of the river is a large area containing forest and agricultural land. The residential neighborhoods north and west of the site, the nursing home, and the recreational fields east of the site would be sensitive noise and vibration receptors.

The city of Taunton recently adopted a Transit Development District zoning overlay at this station site; the zoning at the Taunton Station site is mixed-use (Figure 4.2-21). Zoning near this site is almost entirely moderate-density, single-family residential with an area of general industrial, and an area of limited business.

Whittenton Alternatives Station Sites

The Whittenton Alternatives would involve the same stations as the Stoughton Alternatives, with the exception of the Taunton (Dean St.) station that is bypassed by the Whittenton Alternatives alignment. Instead of a station at Dean St., the Whittenton Alternatives would have a station at Dana Street in Taunton along the Attleboro Secondary. Land uses surrounding the proposed Dana Street station are diverse, and include industrial, residential and agricultural uses (Figure 4.2-39). Zoning districts around the station site include a highway business commercial district, residential districts and a conservation district.

Layover Facilities

Two overnight layover facilities are required for the Build alternatives, one each at or near the end of the Fall River Secondary and the New Bedford Main Lines. A total of five alternative sites were identified in the DEIS/DEIR, three for the Fall River Secondary and two for the New Bedford Main Line. Subsequent to the DEIS/DEIR, MassDOT reviewed the alternative sites and identified the Wamsutta site as their preferred alternative for the New Bedford Line and the Weaver’s Cove East site as their preferred alternative for the Fall River Secondary Line. This section provides basic descriptions of each layover facility site and an indication of its location in reference to existing land uses.

Layover facility plans are conceptual at this point, consisting only of general layouts and footprints. Tracks at the train layover facilities would diverge from the respective through lines (Fall River Secondary, or New Bedford Main Line) and consist of a series of short parallel spurs upon which trains

would be parked for overnight layovers and light maintenance work. Parking areas for employees would be included within the facilities, and hooded lights would minimize light pollution. Small site structures are planned for storage and personnel change rooms. The facilities would be fenced and lighted for security. Conceptual designs for these facilities that have been developed subsequent to the DEIS/DEIR are discussed in Chapter 3, *Alternatives* (Section 3.2.16).

Weaver's Cove East Layover Facility Site

The proposed Weaver's Cove East site layover facility (Figure 4.2-22) would be constructed along the east side of the Fall River Secondary and would serve all Build alternatives. It would be located in Fall River west of Main Street between the existing Fall River Secondary and Main Street, approximately 2.5 miles from the southern terminus of the Fall River Secondary.

Currently vacant land, a portion of the Weaver's Cove East site, was previously developed. Approximately one-half of the site is cleared of vegetation or includes remnant building foundations; the remainder of the site is vegetated. Surrounding land to the north, east, and south is residential; industrial land use is present to the southwest. Undeveloped land is immediately west of the site, adjoining the Taunton River. The industrial site to the southwest is a former Shell Oil facility, and consists of completely cleared land with several large aboveground storage tanks and a short shipping dock.

Wamsutta Layover Facility Site

The proposed Wamsutta site layover facility (Figure 4.2-23) would be constructed along the New Bedford Main Line and would serve all Build alternatives. It would be located in New Bedford near the intersection of Wamsutta Street and Herman Melville Boulevard, near the southern terminus of the New Bedford Main Line, just north of the Whale's Tooth Station.

The Wamsutta site is a previously developed site, currently used as a rail yard for CSX, within an industrial area. The site is visible from adjacent roads and buildings. Adjoining properties are transportation corridors or industrial in nature. Industrial sites are located north, east, and south of this location, and Route 18 to the west. No commercial or residential properties, or open spaces, are located in close proximity to this site.

4.2.3 Analysis of Impacts

4.2.3.1 No-Build (Enhanced Bus) Alternative

The No-Build Alternative (Enhanced Bus) would improve transit service to Boston from New Bedford, Fall River, and Taunton by adding more buses to existing routes. Under this alternative, no new rail or bus service would be provided to Southeastern Massachusetts.

No new construction or land acquisition would be required for the No-Build Alternative. Therefore, the No-Build Alternative would have no direct impacts on land use.

4.2.3.2 Southern Triangle (Common to all Build Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all Build alternatives. These rail lines form a rough triangular shape running south from Myricks Junction to Fall River (the Fall River Secondary) and from Weir Junction through Myricks Junction to New Bedford

(the New Bedford Main Line), and are therefore referred to as the Southern Triangle (Figure 1.4-1). The following sections describe the direct environmental consequences to land uses that may result from new construction for these two common components of the Build alternatives of the South Coast Rail project. The northern part of the South Coast Rail study area is described in subsequent sections for each alternative.

Fall River Secondary

The Fall River Secondary is currently a freight track and would be upgraded and maintained to Federal Rail Administration (FRA) Class 7 options[11] for the South Coast Rail project. The majority of the 12.3-mile-long alignment would be single-track, with a 0.7-mile double-track segment at Myricks Junction and a 1.0-mile double-track section adjacent to the Fall River Golf Club. Three sidings are also proposed in Freetown and Fall River to allow flexibility between commuter and freight operations. The public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. The existing freight service using the Fall River Secondary is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would need to be constructed along the length of the line, and two new traction power facilities would need to be constructed for the electric alternatives. Potential direct impacts to land uses resulting from constructing the upgraded rail lines and electrical infrastructure are described below.

Two new stations would be constructed in Fall River (Battleship Cove and Fall River Depot) and one new station would be constructed in Freetown (Freetown). One new layover facility would be constructed in Fall River, at the Weaver's Cove East site. Potential direct impacts to land uses resulting from constructing the new stations and layover facilities along the Fall River Secondary are considered below in the Stations and Layover facilities sections.

New Bedford Main Line

The 19.4-mile existing New Bedford Main Line freight track would be upgraded to FRA Class 7 options for the South Coast Rail project. Two tracks would be constructed between Weir Junction and Myricks Junction, and with a 0.9-mile third track for freight movements near Taunton Depot Station. A short segment of the line would be double-track south of Myricks Junction, 0.8 mile. The remainder of the line would be single-track, with the exception of a 1.8-mile double-track section in Freetown and a 1.7-mile section in New Bedford. The existing public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. One public at-grade road/railroad crossing would be closed. The existing freight service using the New Bedford Main Line is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would need to be constructed along the length of the line, and four or five traction power facilities (depending upon the alternative selected) would be constructed for the electric alternatives. Potential direct impacts to land resulting from constructing the upgraded rail lines and electrical infrastructure are described below.

Two new train stations would be constructed in New Bedford (Whale's Tooth and King's Highway) and one new train station would be constructed in Taunton (Taunton Depot). One new layover facility would be constructed in New Bedford at the Wamsutta site. Potential direct impacts to land uses resulting from constructing and using the new stations and layover facilities along the New Bedford Main Line are considered below.

---

[11] FRA. 2009. 49 CFR 213.9 Classes of Track: Operating Speed Limits. U.S. Department of Transportation, Federal Railroad Administration.

Property Acquisition

The number, area, public or private ownership, and general land use of parcels that would be acquired in each municipality along the Fall River Secondary right-of-way and New Bedford Main Line right-of-way (i.e., the Southern Triangle) and for the traction power facilities for the electric alternatives, are summarized in Table 4.2-2 and shown in Figures 4.2-1a-d and 4.2-2a-c.

Table 4.2-2 Southern Triangle Land Acquisition: Fall River Secondary and New Bedford Main Line

Municipality	Public Ownership Area in Acres (number of parcels)	Private Ownership Land Use Area in acres (number of parcels)				
		Residential	Commercial	Industrial	Undeveloped	*Subtotal*
Right-of-Way (All Build Alternatives)						
Berkley	**0.03 (1)**	**5.50 (3)**	**-**	**0.30 (1)**	**0.80 (4)**	***6.60 (8)***
Fall River	**0.85 (1)**	**0.04 (2)**	**-**	**-**	**0.03 (1)**	***0.07 (3)***
Freetown	**0.03 (1)**	**0.12 (4)**	**-**	**-**	**0.01 (1)**	***0.13 (5)***
Lakeville	**-**	**-**	**-**	**-**	**0.16 (4)**	***0.16 (4)***
New Bedford	**0.39 (1)**	**-**	**-**	**0.34 (5)**	**-**	***0.34 (5)***
TOTAL (All Diesel Alternatives)	*1.30 (8)*	*5.66 (9)*	*-*	*0.64 (6)*	*1.00 (10)*	*7.30 (25)*
Traction Power Facilities (All Electric Alternatives)						
Berkley	**0.01 (1)**	**-**	**-**	**-**	**-**	**-**
Fall River	**-**	**-**	**-**	**-**	**0.24 (1)**	***0.24 (1)***
Freetown	**-**	**-**	**-**	**-**	**0.18 (1)**	***0.18 (1)***

New Bedford	**-**	**-**	**-**	**-**	**0.89 (1)**	***0.89 (1)***
TOTAL (Right-of-Way and Traction Power Facilities, All Electric Alternatives)	*1.31 (1)*	*5.66 (9)*	*-*	*0.64 (6)*	*2.31 (13)*	*8.61 (28)*

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

The Southern Triangle would require 7.30 acres of land acquisition for the diesel alternatives and 8.61 acres for the electric alternatives. Private property acquisitions include 6.0 acres (17 parcels) for the diesel alternatives, and 7.3 acres (27 parcels) for the electric alternatives. The greatest amount of affected private land along the right-of-way would be residential and undeveloped properties, totaling 5.66 and 1.00 acres, respectively (5.66 and 2.31 acres for the electric alternatives), with minimal impacts to industrial land and no effect on commercial land. Three undeveloped parcels would be affected by the traction power facility sites. The greatest amount of privately-owned land would be acquired in Berkley, and the least in Lakeville. Public property acquisitions include 1.30 acres (8 parcels) for the diesel alternatives, plus an additional 0.01 acre (1 parcel) for the electric alternatives. Public land would be acquired in all affected Southern Triangle municipalities for the right-of-way, with the exception of Lakeville.

Most of the land that would be acquired for the right-of-way or traction power facilities consists of small portions of either publicly or privately owned parcels. No business or community facility displacements would result from the Southern Triangle acquisitions along the Fall River Secondary. Residential displacement would occur in Berkley, from three homes occupying two parcels at Myricks Junction (Figures 4.2-2a). Based on the average Berkley household size of 3.1 persons, nine persons would be displaced by these acquisitions.

The above-mentioned two parcels in Berkley, at Myricks Junction, would be acquired in full. These two parcels are zoned for residential use (but land use is identified as “undeveloped” for one).

4.2.3.3 Stoughton Electric Alternative

The Stoughton Electric Alternative north of the Southern Triangle would be comprised of a portion of the Northeast Corridor and the entire Stoughton Line. This alternative would use the existing Northeast Corridor from South Station to Canton. From Canton Junction, the existing, active Stoughton Line would be used to Stoughton Station. Commuter rail service would be extended, using an out-of-service railroad bed, south through Raynham Junction to Weir Junction in Taunton, at which point this alignment joins the New Bedford Main Line.

This evaluation focuses on the existing and extended Stoughton Line segment; no construction would be required in the Northeast Corridor segment for this alternative, and the Southern Triangle segments were addressed above.

The existing Stoughton Line commuter rail double track from Canton Junction to Stoughton Station, a distance of 3.8 miles, would be upgraded to FRA Class 7 for the Stoughton Electric Alternative. A new double track would extend south of Stoughton Station to the proposed North Easton Station. The remainder of the line south to Weir Junction would be single- track, with a 2.2-mile long double-track section in Raynham, and a 0.6-mile long double-track section in Taunton. Approaching Weir Junction, an additional 0.4 mile siding track would be provided for freight use only. Weir Junction would also be reconfigured to accommodate four tracks as well as 45 MPH for operations through the curve while maintaining existing rail connections. A frontage road would be constructed in Stoughton connecting to Morton Street to eliminate multiple grade crossings, and a new grade-separated crossing is proposed at Route 138 in Raynham. All other existing at-grade road/railroad crossings would be reconfigured and/or improved to meet current safety standards. New catenary supports and wires would be constructed along the length of the line, and three new traction power facilities would be constructed. Potential direct impacts to land uses resulting from constructing the upgraded rail lines and electrical infrastructure are described below.

One existing train station (Canton Center) along the active portion of the Stoughton Line would be reconstructed. The existing Stoughton station would be deactivated and a new Stoughton station would be constructed south of the existing station. A total of five new train stations (Stoughton, North Easton, Easton Village, Raynham Park, and Taunton) would be constructed. No new layover facilities would be constructed along this segment. Potential direct impacts to land uses from reconstructing the existing and developing the new stations along the Stoughton Line are considered below.

Property Acquisition

The number, area, public or private ownership, and general land use of parcels that would be acquired in each municipality along the Stoughton Line right-of-way and for the traction power facilities for the Stoughton Electric Alternative are summarized in Table 4.2-3 and shown in Figures 4.2-3a-e.

Table 4.2-3 Stoughton Alternatives: Land Acquisition

Municipality	Public Ownership Area in Acres (number of parcels)	Private Ownership Land Use Area in acres (number of parcels) Residential	Commercial	Industrial	Undeveloped	Subtotal
Right-of-Way (Stoughton Alternatives)						
Berkley	**<0.1 (1)**	**5.5 (3)**	-	**0.3 (1)**	**0.8 (4)**	***6.6 (8)***
Canton	-		**0.1 (1)**	-	--	***0.1 (1)***

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

This segment would require 43.6 acres (80 parcels) of privately owned land for the right-of-way, plus an additional 1.1 acres (7 parcels) for traction power facilities. The majority of the affected private land along the Stoughton Line right-of-way would be undeveloped property, totaling 16.3 acres, with some impacts to industrial and residential land and little impacts to commercial land. The most area of private land would be acquired in Raynham, with less land acquired in Berkley, Taunton, and Stoughton, and little land acquired in Lakeville, Freetown, New Bedford, Fall River or Canton, and no private land

acquisition in Easton. Moderate areas of undeveloped land would be acquired for traction power facilities in Canton, Freetown, New Bedford, and Fall River, and for the Frontage Road in Stoughton.

Public property acquisitions include 4.1 acres (13 parcels) for the diesel alternatives, plus an additional 1.1 acre (2 parcels) for the electric alternatives. Some public land would be acquired for the right-of-way and traction power facilities in Berkley, Freetown, New Bedford, Fall River, Easton, Stoughton and Taunton. No public land would be affected in Canton, Lakeville or Raynham, where a utility corridor owned by Taunton Municipal Power & Light occupies the former Stoughton track right-of-way.[12] No business or community facility displacements would result from these acquisitions along the Stoughton Line. Residential displacement would occur in Raynham, from one home occupying one parcel south of Raynham Junction (Figure 4.2-3d). Based on the average Raynham household size of 2.8 persons, three persons would be displaced by this acquisition.

Two parcels in Raynham, near Raynham Junction, would be acquired in full. These two parcels are zoned for residential use (but land use is identified as “forest” and “residential”). The residential displacement noted above would be from one of these parcels.

Most of the land that would be acquired for the Stoughton Line right-of-way or traction power facilities consists of small portions of either publicly or privately owned parcels. Eight of the privately owned parcels that would be acquired for the Stoughton Line right-of-way would be acquired in full.

4.2.3.4 Stoughton Diesel Alternative

The Stoughton Diesel Alternative is identical to the Stoughton Electric Alternative with the exception of the locomotive power source. Diesel-powered train service differs from electric-powered service in not requiring electrical infrastructure. Traction power facilities would not be necessary, and the footprint of the area impacted is therefore smaller. The right-of-way subtotal in Table 4.2-3 and areas outlined in Figures 4.2-3a-e show parcel acquisition required for the Stoughton Diesel Alternative.

This segment would require 43.6 acres (80 parcels) of privately owned land and 4.1 acres (13 parcels) of publicly owned land (see Table 4.2-3). The majority of the affected private land along the Stoughton Line right-of-way for the Stoughton Diesel Alternative would be residential property, totaling 15.7 acres (32 parcels). There would be similar impacts to undeveloped property, totaling 15.2 acres (26 parcels), as well as some impacts to industrial land and minor impacts to commercial land. The most area of private land would be acquired in Raynham, with considerably less land acquired in Berkley, Stoughton and Taunton, little land acquired in Lakeville, Freetown, New Bedford, Fall River or Canton, and no private land acquisition in Easton. All other aspects of the Stoughton Diesel Alternative relevant to land uses are the same as for the Stoughton Electric Alternative described in Section 4.2.3.3, above.

4.2.3.5 Whittenton Electric Alternative

The Whittenton Electric Alternative is a variant of the Stoughton Electric Alternative alignment. At Raynham Junction near the southern end of the Stoughton Line, the route would divert to the southwest, following the out-of-service Whittenton Branch. A single track would be constructed along this right-of-way, for a distance of 3.6 miles. The Whittenton Branch connects with the Attleboro Secondary at Whittenton Junction in Taunton; the Attleboro Secondary continues toward the southeast to connect with the New Bedford Main Line at Weir Junction. On this portion of the Attleboro Secondary, 2.2 miles of single-track would be reconstructed, with a 0.3-mile siding reserved for the

[12] The power line would be relocated within the rail corridor or relocated to Route 138.

proposed Dana Street Station. The southernmost portion of the Stoughton Line, from Raynham Junction to Weir Junction (a distance of 5.1 miles), would be not be used if this alternative is selected. This evaluation focuses on the Whittenton Branch and Attleboro Secondary components; other components of this alternative are described above in Sections 4.2.3.2 and 4.2.3.3 (north of Raynham Junction only). New track would be placed on the out-of-service Whittenton Branch railroad bed from Raynham Junction to Whittenton Junction. The existing public at-grade road/railroad crossings would be reconfigured and/or improved to current safety standards. New catenary supports and wires would be constructed along the length of the line. Potential direct impacts to land uses resulting from constructing the upgraded rail lines and electrical infrastructure are described below.

No traction power facilities would be constructed along the Whittenton Branch; a traction power facility required for this alternative would be constructed within the Attleboro Secondary segment. No new stations would be constructed within the Whittenton Branch portion; one new station (Dana Street) would be constructed in Taunton on the Attleboro Secondary segment. No new layover facilities would be constructed along either segment. Land acquisition requirements along the portion of the Attleboro Secondary of the Whittenton Alternative, as noted in the DEIS/DEIR, have been eliminated (other than those related to the Dana Street Station described separately in the section on station property acquisition impacts).

Property Acquisition

The number, area, public or private ownership, and general land use of parcels that would be acquired for the Whittenton Alternatives are shown in Table 4.2-4 and Figures 4.2-4a-b. Table 4.2-4 summarizes the parcels by municipality to be acquired that would be used for the Whittenton Alternatives.

For the right-of-way and traction power facilities, the Whittenton Electric Alternative would require 54.4 acres (83 parcels) of privately owned land from the combination of the Whittenton Branch, the northern portion of the Stoughton Line, and the southeastern portion of the Attleboro Secondary. No residential, business, or community facility displacements would result from these small acquisitions. Although the Whittenton Branch is owned by the Commonwealth, minor acquisitions would be needed along the right-of-way to accommodate ancillary facilities, including traction power facilities. The majority of the affected private land along the Whittenton Branch right-of-way would be undeveloped property, totaling 17.1 acres (32 parcels), with some impacts to residential, commercial or industrial land. The most area of private land would be acquired in Raynham, with considerably less land acquired in Berkley, Taunton and Stoughton, and little land acquired in Canton, Lakeville, Freetown, New Bedford and Fall River.

The Whittenton alternatives would require the acquisition of 3.3 acres (11 parcels) of public land. No public land would be acquired in Canton, Raynham, Taunton, and Lakeville, but would be acquired in the other municipalities along the Whittenton Branch, the northern portion of the Stoughton Line, and the southeastern portion of the Attleboro Secondary. Moderate areas of undeveloped land would be acquired for traction power facilities in Canton, and less land would be acquired for power facilities in Taunton, Freetown, New Bedford, and Fall River.

All property that would be acquired for the Whittenton Branch or relevant segments of the Stoughton Line and Attleboro Secondary right-of-way, or the traction power facilities along the Stoughton Line and Attleboro Secondary, consists of small portions of either publicly or privately owned parcels.

Table 4.2-4 Whittenton Alternatives: Land Acquisition

Municipality	Public Ownership Area in Acres (number of parcels)	Private Ownership Land Use Area in acres (number of parcels)				
		Residential	Commercial	Industrial	Undeveloped	Subtotal
Right-of-Way (Whittenton Alternatives: Whittenton Branch, Stoughton Line & Attleboro Secondary)

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

4.2.3.6 Whittenton Diesel Alternative

The Whittenton Diesel Alternative is identical to the Whittenton Electric Alternative with the exception of the locomotive power source. As described above for the Stoughton Diesel Alternative, diesel-powered train service differs from electric-powered service in not requiring electrical infrastructure, and thus requires a smaller footprint. In the Southern Triangle and along the Stoughton Line (north of Raynham Junction only), the land acquisition impacts of the Whittenton Diesel Alternative would be the same as described for the Stoughton Diesel Alternative. Along the Whittenton Branch, impacts of the Whittenton Diesel Alternative are anticipated to be a similar negligible amount (0.2 acre on 4 parcels). The right-of-way subtotal in Table 4.2-4 and areas outlined in Figures 4.2-4a-b show parcel acquisition required for the Whittenton Diesel Alternative.

The Whittenton Alternatives would require 53.3 acres (76 parcels) of privately owned land and 3.3 acres (11 parcels) of publicly owned land (see Table 4.2-4). The majority of the affected private land along the Whittenton Line right-of-way for the Whittenton Diesel Alternative would be undeveloped property, totaling 16.0 acres (28 parcels). There would be lesser impacts to industrial, residential, and commercial property, and minor impacts to public land. All other aspects of the Whittenton Diesel Alternative relevant to land uses are the same as for the Whittenton Electric Alternative described in Section 4.2.3.5, above.

4.2.3.7 Stations

This section provides basic descriptions of each train and/or bus station and a list of the parcels to be acquired, in whole or in part, to construct or reconstruct these stations for the South Coast Rail project.

Battleship Cove

The Battleship Cove Station would be a new train station constructed along the Fall River Secondary that would serve all Build alternatives. It would be located on Water Street in Fall River, near the southern terminus of the Fall River Secondary (Figure 4.2-24).

The Battleship Cove Station site is a previously developed parcel that is within the Ponta Delgada Plaza. This station would require 0.28 acre (1 parcel) of publicly owned land that MassDOT plans to lease, rather than acquire, from the city of Fall River (parcel number Y-1-3); therefore, no land acquisition would be required for constructing the Battleship Cove Station (Figure 4.2-3b), and there would be no direct effects to land use at this location. No residential, business, or community facility displacements would result from this acquisition for the Battleship Cove Station.

Canton Center

The Canton Center Station is an existing train station along the Stoughton Line that would serve the all Build Alternatives. It is located at 710 Washington Street in Canton. This station would be reconstructed; it would be modified to accommodate a second track. No land acquisition would be required for reconstructing the Canton Center Station (Figure 4.2-25). There would be no direct effects to land at this location.

Canton Junction

The Canton Junction Station is an existing train station at the junction of the Stoughton Line and the Northeast Corridor which would serve all Build alternatives. It is located at the intersection of Beaumont and Sherman Streets in Canton. No land acquisition would be required for the Canton Junction Station (Figure 4.2-26). There would be no direct effects to land uses at this location.

Dana Street Station (Whittenton Alternatives)

The Dana Street Station in Taunton would be a new train station constructed along the Attleboro Secondary that would serve the Whittenton Alternatives. It would be located just south of the Danforth Street grade crossing, within walking distance of downtown Taunton.

The Dana Street Station site in Taunton is currently a vacant lot. The parcels that would be acquired and converted to transportation/utilities land use to construct the Dana Street Station are listed in Table 4.2-5 and shown in Figure 4.2-40.

Table 4.2-5 Downtown Taunton Dana Street Station: Land Acquisition

Parcel Number	Generalized Zoning	General Land Use	Area (acres)	Percent Acquisition
54-171	Industrial	Industrial	0.56	49
54-448	Residential	Industrial	0.44	100
54-449	Residential	Industrial	0.45	100
54-450	Residential	Industrial	0.47	100
54-451	Residential	Industrial	0.48	100
54-452	Residential	Industrial	0.50	100
54-453	Residential	Industrial	0.49	100
54-454	Residential	Industrial	0.35	100
54-455	Residential		0.35	100
Total			4.09	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

The Dana Street Station in would require 100 percent acquisition of 3.53 acres encompassing eight parcels of privately owned land, as well as 49 percent acquisition of one parcel measuring 0.56 acre. These parcels are vacant or appear to have an industrial use, but they are zoned as residential properties. No residential, business, or community facility displacements would result from this acquisition for the Dana Street Station in Taunton.

Easton Village

The Easton Village Station would be a new train station constructed along the Stoughton Line that would serve the Build Alternatives. The Easton Village Station site is on Sullivan Avenue at the transition point to Mechanic Street (near the intersection with Pond Street) in Easton.

The Easton Village Station site is an undeveloped parcel surrounded by industrial and residential development. The land is currently used as a parking lot. No land acquisition would be required for constructing the Easton Village Station (Figure 4.2-3b), and there would be no direct effects to land use at this location.

Fall River Depot

The Fall River Depot Station would be a new train or bus station constructed along the Fall River Secondary to serve all Build alternatives. It would be located near the intersection of North Davol Street and Pearce Street in Fall River.

The Fall River Depot Station site is a previously developed parcel including and surrounded by commercial and industrial development. Parcels that would be acquired and converted to transportation/utilities land use to construct the Fall River Depot Station are listed in Table 4.2-6 and shown in Figure 4.2-28.

The Fall River Depot Station would require 5.11 acres of land, comprised of 4.94 acres (16 parcels) of privately owned land and 0.17 acre (1 parcel) of publicly owned land. Business displacements would result from these acquisitions. Commercial or industrial buildings on five of the parcels listed above would be acquired to construct this station. No residential or community facility displacements would result from these acquisitions for the Fall River Depot Station.

Parcel number O-15-20 is owned by the city of Fall River; all other parcels are privately owned and would be acquired in whole.

Table 4.2-6 Fall River Depot Station: Land Acquisition

O-22-17	Private	Commercial	Commercial	0.04	**100.0**
TOTAL				**5.11**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
1 Parcels O-15-0009 and O-15-0010 are included with Parcel O-15-0008 in Fall River assessor records.
2 Parcel O-22-0017 is included with Parcel O-22-0005 in Fall River assessor records.

Freetown

The Freetown Station would be a new train or bus station constructed along the Fall River Secondary to serve all Build alternatives. It would be located along South Main Street in Freetown.

The Freetown Station site is a previously developed parcel surrounded by low density residential development and undeveloped land. The parcel that would be acquired and converted to transportation/utilities land use to construct the Freetown Station is listed in Table 4.2-7 and shown in Figure 4.2-29.

Table 4.2-7 Freetown Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Area (acres)	Percent Acquisition
233-19	Private	Commercial	Undeveloped	4.18	15

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
TBD To be determined.

The Freetown Station would require acquisition of 4.18 acres (1 parcel, parcel 233-19) of privately owned land. No residential, business, or community facility displacements would result from this acquisition for the Freetown Station. Less than 50 percent of parcel number 233-19 would be acquired for the Freetown Station.

King's Highway

The King's Highway Station would be a new station constructed along the New Bedford Main Line to serve all Build alternatives. It would be located near the intersection of King's Highway and Tarkiln Hill Road in northern New Bedford.

The King's Highway Station site is a previously developed parcel surrounded by industrial development. This station would share a parking lot with adjacent businesses; no land acquisition would be required (Figure 4.2-30). There would be no direct effects to land uses at this location.

North Easton

The North Easton Station would be a new train station constructed along the Stoughton Line that would serve all Build Alternatives. It would be located at 21 Washington Street in Stoughton, behind the Roche Brothers Plaza.

The North Easton Station site is an undeveloped parcel surrounded by commercial development. Parcels that would be acquired and converted to transportation/utilities land use to construct the North Easton Station are listed in Table 4.2-8 and shown in Figure 4.2-31.

The North Easton Station would require 8.81 acres (6 parcels) of privately owned land. No residential, business, or community facility displacements would result from these acquisitions for the North Easton Station.

Table 4.2-8 North Easton Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Area (acres)	Percent Acquisition
1U-1-1	Private	Residential	**Undeveloped**	**1.65**	**8.0**
1U-1-48	Private	Commercial	Undeveloped	**1.00**	**27.0**
060-006	Private	Commercial	Undeveloped	**6.31**	**100.0**
060-008	Private	Commercial	Commercial	**0.59**	**15.0**
060-009	Private	Commercial	Commercial	**0.69**	**20.0**
TOTAL				**10.24**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
TBD To be determined.
Note Additional property tax revenue losses may result from small and/or partial acquisitions that cannot be determined at this phase.

Less than 50 percent of parcel numbers 1U-1-1, 1U-1-48, 060-006, 060-008, and 060-009,would be acquired. More than 50 percent of parcel number 060_006 would be acquired.

Raynham Park

The Raynham Park Station would be a new train station constructed along the Stoughton Line that would serve the Stoughton or Whittenton Alternatives. It would be located at 1958 Broadway in Raynham, at the former Raynham Park Greyhound Track.

The Raynham Park site is a developed parcel surrounded by recreational development and undeveloped land. Parcels that would be acquired and converted to transportation/utilities land use to construct the Raynham Park Station are listed in Table 4.2-9 and shown in Figure 4.2-32.

The Raynham Park Station would require 11.90 acres (2 parcels) of privately owned land. Commercial buildings on parcel number 1-19-1 would be acquired to construct this station. The business present on this parcel is Raynham Park Simulcast Center. A proposal for developing a slots parlor casino on the Simulcast Center property exists at the time of the preparation of the FEIS/FEIR, but the outcome of this proposal is uncertain as there is a competitive process to determine the location of the new casino.[13] No residential, business, or community facility displacements would result from the property acquisitions for the Raynham Park Station.

Table 4.2-9 Raynham Park Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Area (acres)	Percent Acquisition
1-15	**Private**		**Commercial**	**3.09**	**34.0**
1-19-1	**Private**		**Commercial**	**8.81**	**59.0**
TOTAL				**11.90**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
TBD To be determined.
Note Additional property tax revenue losses may result from small and/or partial acquisitions that cannot be determined at this phase.

Less than 50 percent of parcel number 1-15 would be acquired. More than 50 percent of parcel number 1-19-1 would be acquired.

Stoughton

The Stoughton Station would be a new train station along the Stoughton Line that would serve all Build Alternatives. In order to accommodate a second track, the existing Stoughton Station would be shifted from its location between Porter and Wyman Streets to a new location south of the Wyman Street at-grade crossing.

Land uses and zoning designations of the parcels that would be acquired to reconstruct the Stoughton Station are listed in Table 4.2-10 and shown in Figure 4.2-33.

Table 4.2-10 Stoughton Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Area (acres)	Percent Acquisition
053-101	**Private**	**Industrial**	**Industrial**	**1.05**	**100**
053-102	**Private**	**Industrial**	**Commercial**	**4.42**	**100**
054-110	Private	Commercial	Commercial	0.04	2
054-401	Private	Commercial	Commercial	0.01	10
054-406	**Private**	**Industrial**	**Industrial**	**1.90**	**100**
054-407	Private	Industrial	Undeveloped	0.02	10
TOTAL				**7.44**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various)

The Stoughton Station would require 7.44 acres of privately owned industrial, undeveloped and commercial land. Four parcels would be obtained in entirety; 10 percent or less of two other parcels

[13] http://www.bostonglobe.com/metro/2013/06/11/raynham-park-strikes-deal-with-town-over-slot-machine-parlor/1QLjMn7wbBFwoq505pvoeL/story.html

would be acquired. No residential or community facility displacements would result from this acquisition of land for the Stoughton Station. Business displacements would occur and job losses may result on Parcels 053-101, 053-102 and 054-406. A small portion of the parking lot on Parcel 054-110 would be acquired, with no business displacement or job loss. The other two parcels are undeveloped or vacant; business displacements or job losses would not result from acquiring these parcels.

Relocating the Stoughton Station to the Preferred Alternative site would open up 2.5 acres of land for potential redevelopment. MBTA owns this property and it would be released for sale and redevelopment. This land, currently occupied by tracks and parking areas, is on the east side of the proposed tracks.

Taunton (Stoughton Alternatives)

The Taunton Station would be a new train station constructed along the Stoughton Line that would serve the Stoughton Alternatives. It would be located along Arlington Street near Dean Street (Route 44), adjacent to a historic train station in Taunton.

The Taunton Station site is a previously developed parcel surrounded by commercial development. Parcels that would be acquired and converted to transportation/utilities land use to construct the Taunton Station are listed in **Table** 4.2-11 and shown in Figure 4.2-34.

Table 4.2-11 Taunton Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Area (acres)	Percent Acquisition
55-759	Private	Industrial	Undeveloped	1.53	100.0
55-760	Private	Industrial	Undeveloped	7.44	100.0
55-761	Private	Industrial	Undeveloped	0.51	100.0
55-762	Private	Industrial	Undeveloped	0.50	100.0
55-763	Private	Industrial	Undeveloped	0.25	100.0
55-764	Private	Industrial	Undeveloped	0.64	100.0
Pub-ROW	Public	Industrial	Undeveloped	0.95	100.0
TOTAL				**11.82**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

The Taunton Station would require 11.82 acres of land, comprised of 10.87 acres (6 parcels) of privately owned land and 0.95 acre (1 parcel) of publicly owned land. No residential, business, or community facility displacements would result from these acquisitions for Taunton Station.

Parcel number Pub-ROW is owned by the city of Taunton. All seven parcels would be wholly acquired.

Taunton Depot

The Taunton Depot Station would be a new train station constructed along the New Bedford Main Line that would serve all Build alternatives. It would be located at 872 County Street in Taunton, behind the existing Target plaza.

The Taunton Depot Station site is an undeveloped parcel adjacent to commercial development and undeveloped lands. Parcels that would be acquired and converted to transportation/utilities land use to construct the Taunton Depot Station are listed in Table 4.2-12 and shown in Figure 4.2-35.

Table 4.2-12 Taunton Depot Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Area (acres)	Percent Acquisition
107-47	Private	Residential	Commercial	0.56	100.0
107-48	Private	Industrial	Undeveloped	10.97	40.0
TOTAL				**11.53**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

The Taunton Depot Station would require 11.53 acres (2 parcels) of privately owned land. No residential, business, or community facility displacements would result from these acquisitions for the Taunton Depot Station.

Less than 50 percent of parcel number 107-57 would be acquired for the Taunton Depot. Parcel number 107-47 would be wholly acquired.

Whale's Tooth

The Whale's Tooth Station would be a new train station constructed along the New Bedford Main Line constructed to serve all Build alternatives. It would be located near the intersection of Acushnet Avenue and Hillman Street, near the southern terminus of the New Bedford Main Line.

The Whale's Tooth Station site is a previously developed parcel surrounded by industrial development. The city of New Bedford recently constructed a parking lot at this site in anticipation of the proposed South Coast Rail project. No land acquisition would be required for constructing the Whale's Tooth Station (Figure 4.2-3b), and there would be no direct effects to land use at this location (Figure 4.2-36).

4.2.3.8 Layover Facilities

Two overnight layover facilities are planned for the Southern Triangle: one each at or near the end of the Fall River Secondary and the New Bedford Main Line. The Wamsutta site was selected as layover facility for the New Bedford Main Line and Weaver's Cove East was selected for the Fall River Secondary (see Chapter 3). This section provides basic descriptions of each of the selected layover facility sites and a list of the parcels to be acquired, in whole or in part, to construct these facilities for the South Coast Rail project.

Wamsutta

The Wamsutta site layover facility would be constructed along the New Bedford Main Line and would serve all Build alternatives. It would be located in New Bedford near the intersection of Wamsutta Street and Herman Melville Boulevard, near the southern terminus of the New Bedford Main Line, just north of the Whale's Tooth Station.

The Wamsutta site layover facility alternative location is a previously developed site, currently used as a rail yard for CSX, within an industrial area. The parcel that would be acquired to construct a layover facility at the Wamsutta site is shown in Figure 4.2-37.

The layover facility at the Wamsutta site would require 5.90 acres (1 parcel) of publicly owned land. No residential, business, or community facility displacements would result from this acquisition for the Wamsutta site. Parcel number 72-275 is owned by Housing 70 Corporation (the city of New Bedford).

Weaver's Cove

The Weaver's Cove site layover facility would be constructed along the Fall River Secondary and would serve all Build alternatives. It would be located in Fall River west of Main Street between the existing Fall River Secondary and Main Street, approximately 2.5 miles from the southern terminus of the Fall River Secondary.

Currently vacant land, a portion of the Weaver's Cove East site was previously developed. Approximately one-half of the site is cleared of vegetation or includes remnant building foundations; the remainder of the site is vegetated. Surrounding land to the north, east, and south is residential; industrial land use is present to the southwest. Undeveloped land is immediately west of the site, adjoining the Taunton River. The land acquisition necessary to construct a layover facility at the Weaver's Cove East site is shown in Figure 4.2-38.

The layover facility at the Weaver's Cove site would require 18.43 acres (2 parcels) of privately owned land.

More than 50 percent of parcel number T-15-33 would be acquired. Parcel numberT-1-38 would be wholly acquired. Parcel T-15-0033 incorporates Parcel T-15-1 in the city of Fall River Assessor's records. Figure 4.2-38 depicts both parcels.

Summary of Layover Facility Effects

Table 4.2-13 summarizes the land acquisition for the layover facility sites. Private land acquisition would range from 0.0 acres for the Wamsutta site to 18.43 acres for the Weaver's Cove site. The Wamsutta site would require an acquisition of 5.90 acres (1 parcel) of public land.

Table 4.2-13 Summary of Layover Facility Land Acquisition

Layover Facility Site	Public Ownership Area in acres (number of parcels)	Private Ownership Land Use Area in acres (number of parcels)				
		Residential	Commercial	Industrial	Undeveloped	Subtotal
Wamsutta Site	5.90 (1)	-	-	-	5.90 (1)	5.90 (1)
Weaver's Cove Site	-	-	-	-	18.43 (2)	18.43 (2)

4.2.3.9 Summary

The Build Alternatives would all require property acquisitions outside existing rights-of-way to accommodate the new stations and rail infrastructure. Summary tables of property impacts by municipality for the Stoughton Alternatives (Diesel and Electric) and Whittenton Electric Alternative are provided in Tables 4.2-14 and 4.2-15, respectively. The total acreage of land use impacts of the Stoughton Alternatives (134.5 to 136.7 acres) is slightly greater than the total acreage of land use impacts of the Whittenton Alternatives (134.6 to 136.8 acres). The electric versions of each of the rail alternatives require slightly larger amounts of land acquisition than the diesel versions because of the need for traction power substations with the electric alternatives. Property acquisitions and compensation of affected property owners would be conducted in accordance with federal and state requirements.

Table 4.2-14 Stoughton Alternatives: Land Acquisition Summary by Municipality

Municipality	Public Ownership Area in acres (number of parcels)	Private Ownership Land Use Area in acres (number of parcels)

4.3 SOCIOECONOMICS

4.3.1 Introduction

This chapter describes the social and economic environment within and adjacent to the South Coast Rail project corridor and analyzes the impacts to the social and economic environment resulting from implementing each of the South Coast Rail alternatives, including the No-Build Alternative. Background information on the proposed South Coast Rail project and a description of each of the proposed alternatives are provided in Chapter 3, *Alternatives*.

Section 4.3.2 describes the social and economic environment within and adjacent to the South Coast Rail project corridors. The section serves as the baseline for estimating the potential impacts resulting from the South Coast Rail alternatives. The effects to the social and economic environment that may result from implementation of the proposed South Coast Rail alternatives are presented in Sections 4.3.3 and 4.3.4; Section 4.3.3 presents the effect for each element of the proposed alternatives while Section 4.3.4 summarizes the effects for each alternative.

4.3.1.1 Resource Definition

Social and economic characteristics encompass population characteristics and trends as well as economic characteristics and trends. Social and economic characteristics include population, income, housing, property tax revenues, business activity, employment, and unemployment.

4.3.1.2 Regulatory Context

The CEQ NEPA regulations require that an Environmental Impact Statement evaluate a proposed action's impact on the human environment, including "urban quality, historic and cultural resources, and the design of the built environment," including the reuse and conservation potential of various alternatives and mitigation measures.[1] The Corps' public interest review includes economics as a public interest factor (33 CFR § 320.4(a)).

There are no state regulations applicable to the analysis of social and economic effects of a proposed project. The Secretary of the Executive Office of EEA[2] issued a Certificate on the ENF on April 3, 2009. The certificate includes a number of requirements defining the scope of a forthcoming Draft EIR. However, no specific requirements for the evaluation of impacts related to the social and economic environment are included in the Certificate.[3]

4.3.2 Existing Conditions

The following describes the existing conditions within the social and economic environment study area, including population, housing, employment, median income, current economic development tools, and work-trip characteristic trends.

[1] Council on Environmental Quality. 2009. Code of Federal Regulations (CFR), Title 40: Protection of the Environment, Part 1502-Environmental Impact Statement, Section 16(g) Environmental Consequences (40 CFR 1502.16(g)).

[2] Formerly, the Executive Office of Environmental Affairs.

[3] Certificate of the Secretary of Energy and Environmental Affairs on the Environmental Notification Form. South Coast Rail Project. April 3, 2009.

4.3.2.1 Methodology

Social and economic data were collected from the following sources: U.S. Census Bureau, SRPEDD, Metropolitan Area Planning Council (MAPC), Massachusetts Executive Office of Labor and Workforce Development, Central Transportation Planning Staff (CTPS), Claritas, Inc. and the South Coast Rail Economic Development and Land Use Corridor Plan.

All household income data is presented in 1999 dollars. The 1989 median household income data obtained from the 1990 Census of Housing and Population were adjusted for inflation to using the Northeast Urban Consumer Price Index (CPI) to allow for comparison between this data and the 1999 median household income data obtained from Census 2000.

The 2010 U.S. Census results were not available at the time the DEIS/DEIR was prepared. Select indicators from the 2010 Census have been incorporated in this chapter to ensure an up-to-date consideration of socioeconomic trends, while still relying on pre-2010 Census data for the majority of the detailed existing conditions evaluation. It was determined that a complete update of the socioeconomic profile of the study area was not necessary because such an update would not change the overall conclusions about socioeconomic conditions from those presented in the DEIS/DEIR. Although important events such as the 2008 economic recession have impacted the study area, the demographics of the area and the relative economic condition of the municipalities in the study area has not fundamentally changed.

4.3.2.2 Regional Overview

Table 4.3-1 identifies communities included in the regional study area for socioeconomics.[4] This includes 17 municipalities in Bristol County and 3 municipalities in Plymouth County. The alternative railroad alignments pass through or near these 20 communities, and new station sites are within or near each. Social and economic conditions within each of these municipalities, relative to the alternative alignments and station sites, are discussed further below.

Table 4.3-1 Social and Economic Environment Study Area Communities

Acushnet	Fall River	Rehoboth
Attleboro	Freetown	Rochester
Berkley	Lakeville	Somerset
Dartmouth	Mattapoisett	Swansea
Dighton	New Bedford	Taunton
Easton	Norton	Westport
Fairhaven	Raynham	

Southeastern Massachusetts is one of the fastest growing regions within the northeastern United States, and is the fastest growing region in the Commonwealth, based on population and housing units. As communities close to Boston approached build-out and residential and real estate prices increased over the last decade, both the population and the number of Boston-oriented commuters in the South Coast region have increased. In addition, the South Coast area has experienced considerable, but variable

[4] This discussion of South Coast regional communities reflects the DEIS/DEIR socioeconomics study and includes communities associated with alternatives no longer under consideration (i.e., the Attleboro and Rapid Bus Alternatives). Communities associated with alternatives that have been eliminated were retained in the regional study area only for purposes of consistency with the DEIS/DEIR existing conditions analysis and are not considered in the FEIS/FEIR impact analysis (which is focused on the Stoughton and Whittenton Alternatives).

commercial and industrial growth. The South Coast area is also one of the Commonwealth's more diverse regions, and includes older former mill cities, rural towns, and suburban bedroom communities.

Population and housing growth have not been equally distributed, with the historic cities of New Bedford and Fall River experiencing a decline in population for many years, nor has the regional development been matched by a growth in jobs. Known for its seacoast and estuaries, cranberry ponds, rural landscapes that contain globally rare species and environments, and cities with an important role in the nation's economic and cultural past, southeastern Massachusetts more recently has experienced struggling cities, congested highways, and sprawling development, resulting in a loss of green spaces.

Growth-related concerns within the South Coast region include:[5]

- The South Coast region had been growing faster than the Commonwealth as a whole, but this trend has changed and the region is now growing slightly slower than the Commonwealth. Between 1990 and 2006, the region experienced a 10.3 percent increase in population, exceeding the statewide increase of 6.9 percent. U.S. Census Bureau data indicate that the South Coast region population increased from 773,748 in 2000 to 796,306 in 2010, a net increase of 22,558 persons or 2.9 percent. Comparatively, the population of Massachusetts as a whole increased from 6,349,097 in 2000 to 6,547, 629 in 2010, an increase of 3.1 percent.[6]

- The region is part of a "sprawl frontier" of low-density development spreading out from Greater Boston. The communities with the most developable land have the least capacity to manage growth in terms of infrastructure, existing plans and policies, and municipal staff.

- Semi-rural communities located between I-495 and I-195 (including Rehoboth, Dighton, Berkley, and Rochester) are most vulnerable to unplanned growth because they lack infrastructure, land protection for key parcels, and often times town staff to help them plan.

- Fall River and New Bedford continued to lose population during the 1990s. Fall River's population continued to decline in the early 21st century, from 91,938 in 2000 to 88,857 in 2010, a loss of 3,081 persons at a rate of 3.4 percent over these 10 years. New Bedford's population increased in the early 21st century, from 93,768 in 2000 to 95,072 in 2010, a gain of 1,304 persons at a rate of 1.4 percent over these 10 years.[7]

- Residential development tends to first occur as low-density residential development on lots along rural road frontage.

- Although 18 percent of South Coast Rail communities' land is permanently protected, important habitat and resource areas are not yet effectively covered by protected land.

- Although job concentrations continue to be important in South Coast cities, low-density sprawl along major highways also increasingly characterizes business and job locations.

- While many communities have added zoning and other regulatory tools to promote more compact development patterns, in most cases these tools have been little used thus far—in some cases because of recent adoption but also because of market inertia and lack of local capacity to promote new approaches.

- Between 1976 and 2000, job growth in the South Coast region lagged behind Massachusetts, which in turn lagged behind the United States as a whole. Over half the manufacturing jobs in the corridor disappeared, with construction, retail, wholesale trade, and services replacing manufacturing.

- The competitive advantages of the South Coast region today are in costs of production: labor, land, energy, and to a lesser degree, taxes. Lower housing costs help reduce the cost of labor.

- The barriers to economic growth in communities in the vicinity of the South Coast Rail project are access to labor, labor skill levels, quality of broadband service, and access to any intermodal freight rail yard.

- Potential growth industries based on current strengths and overcoming barriers (especially workforce access, education, and broadband service) include: distribution, office-related industries, health care and social services, food processing, hospitality, chemical manufacturing, electronics, and construction.

- Indicators for Fall River and New Bedford show that those communities have significantly lower median household incomes, education levels, housing values and per capita local tax receipts than the South Coast region as a whole.

- The South Coast region has been characterized by ex-urban sprawl, the decline of gateway cities, and the consumption of natural areas at a rate that exceeds the population growth rate. This type of uncontrolled growth results in the loss of farms, fields, and forests and damages the character of the historic villages and cities within the region.

- The poor connectivity to the metropolitan Boston area may constrain economic activity in the urban areas of New Bedford and Fall River. These two cities currently have higher unemployment rates than the state average. In 2007, the New Bedford metropolitan area had an unemployment rate of 7.6 percent, while Fall River had an unemployment rate of 8.3 percent. The state average was 4.5 percent.[8] By 2010, unemployment had risen to 14.5 percent in Fall River and 14.0 percent in New Bedford, compared to 8.3 percent statewide.[9]

Affected Municipalities

The following section summarizes, by municipality, general social and economic conditions within the South Coast region. Table 4.3-2 summarizes the population statistics for these communities. Table 4.3-3 summarizes housing trends. Table 4.3-4 summarizes employment statistics. Table 4.3-5 provides a summary of work trips to Boston/Cambridge from these communities. Workforce traveling to

Boston/Cambridge from these communities as compared to the workforce along the Fitchburg Commuter Line is summarized in Table 4.3-6. Table 4.3-7 summarizes household income. Table 4.3-8 provides employment statistics by industry. Property tax rates are summarized in Table 4.3-9.

Acushnet

Acushnet is a mostly rural and suburban town. It had an estimated population of 10,622 in 2006, which represented a 4.5 percent increase since 2000. The number of occupied housing units in Acushnet increased 10.6 percent between 1990 and 2000, corresponding to a 6.4 percent increase in population during this period. The median household income increased from approximately $48,210 in 1989 (in 1999 dollars) to approximately $51,500 in 1999, which corresponds to an annual growth rate of 0.66 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Acushnet was 5.4 percent, exceeding the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 10.2 percent, exceeding statewide unemployment of 8.4 percent. Acushnet's unemployment rate also exceeded the statewide average in 1990 and 2000. In 2005, property tax rates in Acushnet were 12.71 (expressed as dollars per $1,000 of assessed value) for commercial and industrial property, and 10.9 for residential property.

Attleboro

Attleboro is a suburban community in the South Coast region. It had an estimated population of 43,836 in 2006. The number of occupied housing units in Attleboro increased 12.3 percent between 1990 and 2000, while population increased only 9.6 percent during this period. The median household income increased from approximately $49,421 in 1989 (in 1999 dollars) to approximately $50,807 in 1999, which corresponds to an annual growth rate of 0.28 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Attleboro was 4.9 percent, slightly higher than the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 10.8 percent, exceeding statewide unemployment of 8.4 percent. In 2005, property tax rates in Attleboro were $16.57/$1,000 assessed value for commercial and industrial property, and $10.09/$1,000 assessed value for residential property.

Berkley

Berkley is a mostly rural town, with suburban neighborhoods along its northern border. It had an estimated population of 6,476 in 2006, which represented a 12.7 percent increase since 2000. The number of occupied housing units in Berkley increased 36.3 percent between 1990 and 2000, corresponding to a 35.7 percent increase in population during this period. The median household income decreased from approximately $58,024 in 1989 (in 1999 dollars) to approximately $56,170 in 2000, which corresponds to an annual growth rate of -0.32 percent, which is well below the statewide annual growth rate of 0.13 percent. While the unemployment rate in Berkley in 1990 exceeded the statewide average, the 2007 unemployment rate was 4.0 percent, lower than the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 8.2 percent, slightly below the statewide rate of 9.4 percent. In 2005, the property tax rate in Berkley was $17.82/$1,000 assessed value (residential, commercial, and industrial).

Dartmouth

Dartmouth is a mostly rural town with a strip of suburban neighborhoods in its northern/central region. It had an estimated population of 31,466 in 2006, which represented a 2.6 percent increase since 2000.

The number of occupied housing units in Dartmouth increased 14.9 percent between 1990 and 2000, corresponding to a 12.6 percent increase in population during this period. The median household income increased from approximately $47,406 to approximately $50,742 between 1989 and 1999 (both in 1999 dollars), which corresponds to an annual growth rate of 0.68 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Dartmouth was 5.5 percent, exceeding the statewide unemployment rate of 4.5 percent. By 2009, unemployment had risen to 9.6 percent, exceeding statewide unemployment of 8.4 percent. In 2005, the property tax rate in Dartmouth was $7.45/$1,000 assessed value (residential, commercial, and industrial).

Dighton

Dighton is a mostly rural town. It had an estimated population of 6,652 in 2006, which represented a 7.7 percent increase since 2000. The number of occupied housing units in Dighton increased 14.2 percent between 1990 and 2000, corresponding to a 9.7 percent increase in population during this period. The median household income increased from approximately $55,068 to $58,600 between 1989 and 1999 (both in 1999 dollars), which corresponds to an annual growth rate of 0.62 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Dighton was 4.5 percent, which was also the statewide unemployment rate. By 2009, unemployment had risen to 8.8 percent, slightly above the statewide unemployment rate of 8.4 percent. In 2005, the property tax rates in Dighton were $20.8/$1,000 assessed value for commercial and industrial property, and $10.66/$1,000 assessed value for residential property.

Easton

Easton is a mostly suburban town. It had an estimated population of 23,099 in 2006, which represented a 3.6 percent increase since 2000. The number of occupied housing units in Easton increased 11.6 percent between 1990 and 2000, corresponding to a 12.6 percent increase in population during this period. The median household income increased from approximately $68,330 in 1989 (in 1999 dollars) to approximately $69,144 in 1999, which corresponds to an annual growth rate of 0.12 percent, which is about the same as the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Easton was 3.7 percent, lower than the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 7.4 percent but was still lower than the statewide average of 8.4 percent. In 1990 and 2000 Easton also exhibited a lower unemployment rate than the state as a whole. In 2005, the property tax rate in Easton was $7.45/$1,000 assessed value (residential, commercial and industrial).

Fairhaven

Fairhaven is a mostly suburban town, with urban development at its western border and rural neighborhoods in the northeast corner. It had an estimated population of 16,340 in 2006, which represented a 1.1 percent increase since 2000. The number of occupied housing units in Fairhaven increased 4.1 percent between 1990 and 2000, despite a decrease in population of 0.2 percent during this period. After adjusting for inflation, median household income decreased from approximately $40,605 in 1989 (in 1999 dollars) to approximately $36,447 in 1999, which corresponds to an annual growth rate of -1.07 percent, which is well below the statewide annual growth rate of 0.13 percent. In both years, median household income was significantly below the statewide median of $49,850 and $50,500 (both in 1999 dollars), respectively. The 2007 unemployment rate in Fairhaven was 5.6 percent, exceeding the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 10.4 percent, exceeding the statewide average of 8.4 percent. Fairhaven's unemployment rate also

exceeded the statewide average in 1990 and 2000. In 2005, the property tax rates in Fairhaven were $16.66/$1,000 assessed value for commercial and industrial property, and $8.35/$1,000 assessed value for residential property.

Fall River

The southern portion of Fall River is highly developed and urban, while the northern portion is rural. Fall River had an estimated population of 92,516 in 2006, which represented a 0.6 percent increase since 2000. With a population size similar to New Bedford, Fall River is one of the two largest municipalities in the South Coast region in terms of population, accounting for 18 percent of South Coast population. The number of occupied housing units in Fall River increased 4.0 percent between 1990 and 2000, despite a decrease in population of 0.8 percent during this period. The median household income decreased from approximately $30,291 in 1989 (in 1999 dollars) to approximately $29,014 in 1999, which corresponds to an annual growth rate of -0.43 percent, which is well below the statewide annual growth rate of 0.13 percent. In both years, median household income was significantly below the statewide median of $49,850 and $50,500 (both in 1999 dollars), respectively. The 2007 unemployment rate in Fall River was 8.3 percent, significantly exceeding the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 14.6 percent, exceeding the statewide average of 8.4 percent. Fall River's unemployment rate also significantly exceeded the statewide average in 1990 and 2000. In 2005, the property tax rates in Fall River were $19.5/$1,000 assessed value for commercial and industrial property, and $7.61/$1,000 assessed value for residential property.

Freetown

Freetown is mostly rural. It had an estimated population of 9,145 in 2006, which represented a 7.9 percent increase since 2000. The number of occupied housing units in Freetown increased 7.8 percent between 1990 and 2000, despite a decrease in population of 0.6 percent during this period. The median household income increased from approximately $61,382 in 1989 to approximately $64,576 in 1999, which corresponds to an annual growth rate of 0.51 percent, which exceeds the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Freetown was 4.7 percent, slightly exceeding the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had increased to 8.8 percent, slightly exceeding the statewide average of 8.4 percent. In 2005, the property tax rates in Freetown were $15.47/$1,000 assessed value for commercial and industrial property, and $9.88/$1,000 Assessed Value for residential property.

Lakeville

Lakeville is a mixed suburban and rural community. It had an estimated population of 10,699 in 2006, which represented an 8.9 percent increase since 2000. The number of occupied housing units in Lakeville increased 26.4 percent between 1990 and 2000, corresponding with an increase in population of 26.2 percent during this period. The median household income increased from approximately $60,524 in 1989 (in 1999 dollars) to approximately $70,495 in 1999, which corresponds to an annual growth rate of 0.51 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Lakeville was 4.2 percent, slightly lower than the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 8.7 percent, slightly exceeding the statewide average of 8.4 percent. In 2005, the property tax rate in Lakeville was $9.14/$1,000 assessed value (residential, commercial, and industrial).

Mattapoisett

Mattapoisett is a semi-rural community. It had an estimated population of 6,519 in 2006, which represented a 4.0 percent increase since 2000. The number of occupied housing units in Mattapoisett increased 13.4 percent between 1990 and 2000, corresponding with an increase in population of 7.1 percent during this period. The median household income increased from approximately $54,596 in 1989 (in 1999 dollars) to approximately $58,466 in 1999, which corresponds to an annual growth rate of 0.69 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Mattapoisett was 3.8 percent, lower than the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 7.1 percent but was still significantly below the statewide average of 8.4 percent. In 2005, the property tax rate in Mattapoisett was $9.42/$1,000 assessed value (residential, commercial, and industrial).

New Bedford

New Bedford is a highly developed urban city, with some semi-rural communities in its northwestern portion. It had an estimated population of 93,957 in 2006, which represented a 0.2 percent increase since 2000. With a population size similar to Fall River, New Bedford is the largest municipality in the South Coast region in terms of population, each account for 18 percent of South Coast population. The number of occupied housing units in New Bedford decreased 1.6 percent between 1990 and 2000, corresponding to a 6.2 percent decline in population during this period. The median household income decreased from approximately $30,554 in 1989 (in 1999 dollars) to approximately $27,569 in 1999, which corresponds to an annual growth of -1.02 percent, well below the statewide growth rate of 0.13 percent. In both years, median household income was significantly below the statewide median of $49,850 and $50,500 (both in 1999 dollars), respectively. The 2007 unemployment rate in New Bedford was 7.6 percent, significantly exceeding the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 14.2 percent, significantly exceeding the statewide average of 8.4 percent. New Bedford’s unemployment rate also significantly exceeded the statewide average in 1990 and 2000. In 2005, the property tax rates in New Bedford were $27.6/$1,000 assessed value for commercial and industrial property, and $11.37/$1,000 assessed value for residential property.

Norton

Norton is a mixed suburban and rural town. It had an estimated population of 19,637 in 2006, which represented an 8.9 percent change since 2000. The number of occupied housing units in Norton increased 26.5 percent between 1990 and 2000, corresponding to a 26.4 percent increase in population during this period. The median household income decreased from approximately $59,175 to approximately $55,325 between 1989 and 1999 (both in 1999 dollars), which corresponds to an annual growth of -0.67 percent, well below the statewide growth rate of 0.13 percent. The 2007 unemployment rate in Norton was 4.7 percent, similar to the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 8.9 percent, exceeding the statewide average of 8.4 percent. In 2005, the property tax rate in Norton was $10.72/$1,000 assessed value (residential, commercial, and industrial).

Raynham

Raynham is a mixed suburban and rural town. It had an estimated population of 13,805 in 2006, which represented a 17.6 percent change since 2000. The number of occupied housing units in Raynham increased 23.6 percent between 1990 and 2000, corresponding to a 19.0 percent increase in population

during this period. After adjusting for inflation, median household income remained stable from approximately $60,504 in 1989 (in 1999 dollars) to approximately $60,449 in 1999, which corresponds to an annual growth of -0.01 percent, which is less than the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Raynham was 4.1 percent, lower than the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 8.1 percent, slightly below the statewide average of 8.4 percent. In 2005, the property tax rates in Raynham were $13.42/$1,000 assessed value for commercial and industrial property, and $10.25/$1,000 assessed value for residential property.

Rehoboth

Rehoboth is a semi-rural town with an estimated population of 11,020 in 2006, which represented an 8.3 percent change since 2000. The number of occupied housing units in Rehoboth increased 22.8 percent between 1990 and 2000, corresponding to a 17.5 percent increase in population during this period. The median household income increased from approximately $60,667 in 1989 to approximately $65,373 in 1999, which corresponds to an annual growth rate of 0.75 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Rehoboth was 4.3 percent, similar to the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 9.6 percent, exceeding the statewide average of 8.4 percent. In 2005, the property tax rate in Rehoboth was $8.86/$1,000 assessed value (residential, commercial, and industrial).

Rochester

Rochester is a semi-rural town with an estimated population of 5,158 in 2006, which represented a 12.63 percent increase since 2000. The number of occupied housing units in Rochester increased 22.3 percent between 1990 and 2000, corresponding to a 16.8 percent increase in population during this period. The median household income increased from approximately $56,664 to approximately $63,289 between 1989 and 1999 (both in 1999 dollars), which corresponds to an annual growth rate of 0.75 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Rochester was 4.0 percent, lower than the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 7.7 percent, lower than the statewide average of 8.4 percent. In 2005, the property tax rate in Rochester was $9.21/$1,000 assessed value (residential, commercial, and industrial).

Somerset

Somerset is a mostly urban community. It had an estimated population of 18,747 in 2006, which represented a 2.8 percent change since 2000. The number of occupied housing units in Somerset increased 9.0 percent between 1990 and 2000, corresponding to a 3.3 percent increase in population during this period. The median household income increased from approximately $49,133 in 1989 (in 1999 dollars) to approximately $51,770 in 1999, which corresponds to an annual growth rate of 0.52 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Somerset was 5.5 percent, exceeding the statewide unemployment rate of 4.5 percent. Somerset's unemployment rate also exceeded the statewide average in 1990 and 2000. By 2009, the unemployment rate had risen to 10.6 percent, exceeding the statewide average of 8.4 percent. In 2005, the property tax rates in Somerset were $25.15/$1,000 assessed value for commercial and industrial property, and $10.73/$1,000 assessed value for residential property.

Swansea

Swansea is a mixed rural and suburban town. It had an estimated population of 16,622 in 2006, which represented a 4.5 percent change since 2000. The number of occupied housing units in Swansea increased 12.1 percent between 1990 and 2000, corresponding to a 3.2 percent increase in population during this period. The median household income decreased from approximately $54,124 in 1989 (in 1999 dollars) to approximately $52,524 in 1999, which corresponds to an annual growth rate of -0.30 percent, well below the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Swansea was 5.6 percent, exceeding the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 11.2 percent, exceeding the statewide average of 8.4 percent. Swansea's unemployment rate also exceeded the statewide average in 1990 and 2000. In 2005, the property tax rates in Swansea were $16.36/$1,000 assessed value for commercial and industrial property, and $8.09/$1,000 assessed value for residential property.

Taunton

Taunton is a mixed urban/suburban/rural city, with a highly developed urban center. It had an estimated population of 56,732 in 2006, which represented a 1.4 percent increase since 2000. About 11 percent of the South Coast population lives in Taunton. The number of occupied housing units in Taunton increased 17.0 percent between 1990 and 2000, corresponding to a 12.3 percent increase in population during this period. The median household income decreased from approximately $43,600 in 1989 (in 1999 dollars) to approximately $42,932 in 1999, which corresponds to an annual growth rate of -0.30 percent, well below the statewide annual growth rate of 0.13 percent. In both years, median household income was below the statewide median of $49,850 and $50,500 (both in 1999 dollars), respectively. The 2007 unemployment rate in Taunton was 5.0 percent, exceeding the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 9.8 percent, exceeding the statewide average of 8.4 percent. In 2005, the property tax rates in Taunton were $18.1/$1,000 assessed value for commercial and industrial property, and $8.64/$1,000 assessed value for residential property.

Westport

Westport is a primarily semi-rural town, with suburban development along its northern border. It had an estimated population of 15,366 in 2006, which represented an 8.3 percent increase since 2000. The number of occupied housing units in Westport increased 8.8 percent between 1990 and 2000, corresponding to a 2.4 percent increase in population during this period. The median household income increased from approximately $50,042 to approximately $55,436 between 1989 and 1999, which corresponds to an annual growth rate of 0.52 percent, exceeding the statewide annual growth rate of 0.13 percent. The 2007 unemployment rate in Westport was 6.1 percent, exceeding the statewide unemployment rate of 4.5 percent. By 2009, the unemployment rate had risen to 11.1 percent, exceeding the statewide average of 8.4 percent. Westport's unemployment rate also exceeded the statewide average in 1990 and 2000. In 2005, the property tax rate in Westport was $6.14/$1,000 assessed value (residential, commercial, and industrial).

Demographic Trends

In 1990, the total population of the social and economic environment study area was approximately 469,229. In 2000, the population within the study area was 492,366.[10] By 2006, population within this

[10] United States Census Bureau, 1990 and 2000.

area is estimated to have grown to 508,414.[11] Table 4.3-2 summarizes population trends for the communities within the social and economic environment study area. Figure 4.3-1 shows which municipalities experienced population growth between 1990 and 2006 and which experienced population decline during that same period. While Fall River and New Bedford did not experience population decline between 2000 and 2006, they lost population during the nineties.

Table 4.3-2 South Coast Communities: Population Trends

				Percent Change		
Town	**1990**	**2000**	**2006***	**1990 to 2000**	**2000 to 2006**	**1990 to 2006**

Source: U.S. Census (1990, 2000); Claritas, Inc. provided by Goody Clancy (2006
* Indicates projected populations, not actual numbers.

U.S. Census Bureau data indicate that the South Coast region population increased from 773,748 in 2000 to 796,306 in 2010, a net increase of 22,558 persons or 2.9 percent. Comparatively, the population of Massachusetts as a whole increased from 6,349,097 in 2000 to 6,547, 629 in 2010, an increase of 3.1 percent, and the population of Rhode Island increased from 1,048,319 to 1,052,567, or 0.4 percent. The population increase in the South Coast region during this period was comparable to that of Massachusetts, but substantially greater than that of Rhode Island. The population density in 2000 for the study area, based on data from MassGIS and the U.S. Bureau of Census, is shown on Figure 4.3-2.

Concurrent with population growth within the study area, the median age is increasing in these communities at a rate of approximately 9 percent (between 1990 and 2000)[12] and is expected to

[11] 2006 Population estimated using Claritas, Inc., provided by Goody Clancy. It is assumed that populations estimated with Claritas are not exact, but rather +/- 10 percent.

[12] Southeastern Regional Planning and Economic Development District's Community Quickstats, based on U.S. Census Bureau data from 1990 and 2000, compiled summer 2007.

continue to increase in coming years. Growth is anticipated to be greatest in semi-rural and suburban portions of the social and economic environment study area where there is less development; therefore, more land is available for growth than in the more urban communities.[13]

Housing

The increase in population within the study area has been accompanied by an increase in the number of occupied housing units. According to the U.S. Bureau of Census, the number of housing units increased by 8.7 percent in the nineties, from 174,408 in 1990 to 189,634 in 2000. As the region continues to grow and more people move into the area, the number of occupied housing units is projected to increase at an even larger rate. It is estimated that by the year 2030, occupied housing units will have increased by almost 34 percent to reach 208,767. The communities of Berkley, Rehoboth, and Rochester are projected to grow by more than 50 percent. Nine of the 20 communities are expected to see growth in excess of 30 percent. Table 4.3-3 summarizes the occupied housing unit trends and percent change from 1990 to 2000 for the 20 communities comprising the South Coast Rail social and economic environment study area.

Table 4.3-3 South Coast Communities: Occupied Housing Units

Source: U.S. Census (1990, 2000)

In general, residential housing density within the study area is low. Housing density within the study area, based on U.S. Census Bureau 2000 data, is depicted on Figure 4.3-3.[14] Fall River, New Bedford, and

[13] Massachusetts Executive Office of Transportation and Massachusetts Office of Housing and Economic Development. South Coast Rail Economic Development and Land Use Corridor Plan. June 2009. Prepared by Goody Clancy: Boston.

[14] Massachusetts Executive Office of Transportation and Massachusetts Office of Housing and Economic Development. South Coast Rail Economic Development and Land Use Corridor Plan. June 2009. Prepared by Goody Clancy: Boston.

Taunton have the highest housing densities in the study area, while Lakeville, Berkley, Rehoboth, Westport, and Dartmouth are among those with the lowest housing densities. In general, the social and economic environment study area consists primarily of lower-density development characteristic of semi-rural communities. The lot size requirement in many of the communities is large (up to 2 acres) and there are limited multi-family housing units, both factors contributing to lower housing densities.

Economic Indicators

This section presents trends in business establishments, employment, and wages for the study area. These trends cover 1990 to 2007 and were developed primarily from data prepared by the U.S. Census Bureau (1990 and 2000 Census data) and SRPEDD Community Quickstats for communities comprising the South Coast region.

Employment

The population and housing statistics indicate that the region has seen significant growth over the last fifteen years. Employment concentrations (2007) within the study area are presented on Figure 4.3-4. In 2007, businesses were concentrated around cities and large towns as well as along major highways and state routes.[15] As observed by Goody Clancy, "Businesses line nearly the entire stretch of U.S. 44 through the middle of the [South Coast Rail] Corridor; although as shown by the lighter shades [on Figure 4.3-4] densities are low, which indicates sprawling commercial development."[16] This same pattern can be observed along Routes 79 and 24, north of Fall River, a portion of Route 140, north of New Bedford, as well as in the immediate vicinity of exits along I-95 and I-495.

The region's growth has been accompanied by high unemployment rates. Table 4.3-4 shows historical unemployment rates for the communities in the social and economic environment study area, as well as the statewide unemployment rate. The table compares the unemployment rates for 1990, 2000 2007 and 2009 in the study area municipalities to the statewide unemployment rates in the same years.

The table indicates that in 1990 and 2000, the number of cities and towns in the region with unemployment higher than the state average was 16 and 12, respectively. In general, the inequality between the regional and statewide unemployment decreased between 1990 and 2007, but in 2007, 12 communities still had average unemployment rates higher than the state average. By 2009, a total of 15 communities had average unemployment rates higher than the state average. Unemployment rates in Fall River and New Bedford are substantially higher than the statewide average. By 2010, unemployment had risen to 14.5 percent in Fall River and 14.0 percent in New Bedford, compared to 8.3 percent statewide.[17]

Table 4.3-4 shows a decline in the discrepancy between local unemployment and statewide unemployment between 1990 and 2007 for all study area municipalities with the exception of Swansea and Westport. The increased number of South coast residents commuting to the Boston metropolitan area could provide a partial explanation for this decline. Table 4.3-5 shows that work trips from South Coast communities to Boston and Cambridge increased by nearly 39 percent between 1990 and 2000. The change in work trips to Boston and Cambridge from communities within the social and economic

environment study area is shown graphically on Figure 4.3-5. Comparing 1990 to 2009 shows that six communities experienced an increase in the discrepancy between their unemployment and statewide unemployment, including Lakeville and Rehoboth, which in 1990 had unemployment rates below the statewide average.

Source: Massachusetts Executive Office of Labor and Workforce Development website, viewed August 2008 (viewed February 2009 for Attleboro) (these data were not seasonally adjusted).
Bold indicates above state average.

The growth in work trips to the metropolitan Boston job market, as well as the projected increase in population and housing, reflect the movement of affordable housing units further from the urban core job market. Because of the growing congestion on Route 24, it is likely that a substantial portion of commuters destined for the Boston job market would be interested in using the proposed transit service.

Each of the communities evaluated reported an increase in the number of work-related commuters traveling to Boston and Cambridge between 1990 and 2000. Six of the communities reported growth of greater than 100 percent. Lakeville reported the most growth with over 250 percent more workers commuting to Boston and Cambridge in 2000 than in 1990. This increase may, in part, be attributed to the Middleborough/Lakeville commuter rail station, which opened in 1997. Acushnet and New Bedford had the smallest increase, at less than 10 percent between 1990 and 2000.

Table 4.3-6 provides a place of employment comparison between towns in the social and economic environment study area and those along the Fitchburg Line, which is comparable in terms of distance from Boston. The table shows that in 2000, approximately four percent of all work trips originating from within the social and economic environment study area were to the Boston/Cambridge area, while along the Fitchburg Line corridor 8.5 percent of work trips were to Boston or Cambridge.

Median Household Income

Eight communities within the social and economic environment study area reported median household incomes below the statewide average in 1990; however, by 2000 only four municipalities were below the statewide average. Fairhaven, Fall River, New Bedford, and Taunton each reported median household incomes well below the statewide average in both 1989 and 1999 (Table 4.3-7). Even though the number of communities with median household incomes below the statewide average decreased, a total of eight South Coast communities experienced a decline (after adjusting for inflation) in median household income between 1989 and 1999 while statewide median household income showed annual modest increase (i.e., an annual growth rate of 0.14 percent). With negative annual growth rate of more than one percent (-1.07 percent in Fall River, and -1.02 percent in New Bedford), the gap between these communities and the statewide average is broadening substantially.

Table 4.3-7 South Coast Communities: Median Household Income

Town	1989*	1999	Annual Growth 1989-1999

Regional Average Income**	$42,147	$42,736	0.14%

Source: 1990 Census of Housing and Population, Census 2000
* In 1999 dollars, adjusted for inflation using the Northeast Urban CPI.; **Bold** indicates below state average
** Regional Average Income was calculated as the weighted average of the median household incomes in the study area municipalities.

After adjusting for inflation, the regional average household income exhibited an annual increase of 0.14 percent between 1989 and 1999, similar to the statewide increase. The regional average household income was calculated as the average of the median household incomes of the study area municipalities, weighted by the number of households in each municipality.

Household income in the South Coast region increased from an average of $53,532 in 2000 to $77,237 in 2010, a rise of 36.5 percent. Comparatively, average household income in Massachusetts increased from $50,502 in 2000 to $65,981 in 2010, a rise of 30.7 percent.[18]

Industry Trends

The working population within the South Coast region is employed in a variety of industries, as summarized in Table 4.3-8. Industries consistent among all (or nearly all) communities include

[18] USCB "American Fact Finder, Community Facts" website, available at http://factfinder2.census.gov/faces/nav/jsf/pages/index.xhtml

construction; manufacturing; wholesale trade; retail trade; professional and technical services; art, entertainment, and recreation; and accommodation and food service.

The majority of workers in the South Coast region are employed in blue collar and service jobs such as construction, manufacturing, retail trade, health care/social assistance, and accommodation and food service. A large portion of the population is also employed in educational service jobs, particularly towns with higher median incomes, such as Rochester, Lakeville, and Rehoboth. Workers in the larger South Coast cities, such as Fall River and New Bedford are concentrated in the manufacturing and health care/social assistance sector.

Per Capita Local Tax Receipts and Property Tax Rates

Communities within the social and economic environment study area generally exhibit lower land and housing values, with some of these communities also having relatively low levels of per capita property tax receipts, as compared to the Commonwealth as a whole.[19] An evaluation of per capita property tax receipts and property value may be used as a means of assessing a community's economic prosperity, and particularly its ability to finance local government services. In general, the South Coast region ranks well below the statewide average of local tax receipts per capita owing to the relatively low levels of property tax receipts within several communities. Of the South Coast municipalities within the study area, Fall River and New Bedford rank low on both measures, compared to other communities within the South Coast region. Fall River, New Bedford, and Taunton have a greater balance between residential and commercial property tax receipts compared to the South Coast region as a whole, even as their receipts per capita for commercial property are well below the statewide average.[20]

Lower property tax receipts per capita do not necessarily reflect lower tax rates, and therefore are not a measure of potential competitive advantage for attracting new households or businesses. Property tax rates within the study area vary greatly and are summarized in Table 4.3-9. New Bedford, Somerset, Dighton, Fall River, and Taunton have the highest property and commercial/industrial tax rates within the study area. However, residential tax rates within these communities vary, ranging from 7.61 in Fall River, the third lowest residential rate, to 11.37 in New Bedford, the highest residential tax rate in the region. After New Bedford, the highest residential tax rates are in Acushnet, Attleboro, Somerset, Norton, Easton, and Dighton. Tax rates are expressed as dollars per $1,000 of assessed value.

Economic Development Tools

With unemployment on the rise, economic development tools are important to maintaining stability within the social and economic environment study area communities. Where not already in place, approaches have been established, or are planned for several of the communities within the study area. Such tools often are developed within local offices such as redevelopment authorities and economic/industrial development commissions. The municipalities of Attleboro, Fall River, New Bedford, and Taunton have redevelopment authorities. Economic or industrial development commissions are operating in Dartmouth, Dighton, Freetown, New Bedford, Norton, Raynham, Rehoboth, Somerset, Swansea, and Taunton.

Tax Increment Financing (TIF) and District Improvement Financing (DIF) are methods used to promote economic development and redevelopment in communities using public/private partnerships.[21] TIF programs provide tax exemptions of up to 100 percent of the tax increment to individual landowners and developers for projects that have been deemed to be within Economic Opportunity Areas.[22,23] The

[21] Massachusetts Executive Office of Transportation and Massachusetts Office of Housing and Economic Development. South Coast Rail Economic Development and Land Use Corridor Plan. June 2009. Prepared by Goody Clancy: Boston.
[22] Ibid.
[23] Economic Opportunity Areas are determined by the Massachusetts Economic Assistance Coordinating Council (EACC).

implementation of a DIF allows a city or town to designate development districts that use the increased tax revenues derived from new development to fund district-wide improvements, such as streetscape or storefront projects.[24]

Based on information from the Massachusetts Economic Assistance Coordinating Council (EACC), TIF programs apply to projects associated with Economic Opportunity Areas. Such programs provide individuals (landowners and developers) with tax exemptions of as much as 100 percent of the tax increment.[25]

TIFs can be used to maintain existing businesses as well as to create or encourage new businesses. DIF programs differ from TIFs in that they allow cities/towns "to designate development districts that use the increased tax revenues derived from new development (the increment), to specifically fund district-wide improvements, often in the form of streetscape and storefront projects."[26]

Seventeen of the 20 communities within the study area offer TIF programs. Easton, Rehoboth, and Swansea do not currently offer such a program. New Bedford has offered TIF programs since 1997.[27] Currently 77 businesses within the city use TIF, which has resulted in 2,750 jobs for New Bedford. Additionally, a DIF has been utilized in New Bedford to facilitate the revitalization of a 130-acre area (Hicks-Logan Sawyer area) near downtown New Bedford, off I-195.[28] More suburban towns, such as Dartmouth and Attleboro, have also benefited from the use of TIFs, which have facilitated new jobs and new construction within each of these towns.

Summary

As a whole, the communities within the study area have a growing population and growing demand for housing, although Fall River and New Bedford, the two largest cities in the study area in terms of population have seen the least growth over the past 20 years. The analysis shows that the region's population is projected to increase by approximately 30 percent by 2030. However, the region also has higher unemployment rates than the state average, indicating that residents lack access to employment markets. Real median household incomes increased in more than half of the South Coast communities and the number of communities with a median household income below the statewide household income decreased from eight to four. Work trips to Boston have increased by 38 percent over the period 1990-2000, but are still only approximately four percent of all work trips. This is substantially lower than the percentage of work trips to Boston of other communities with rail access, such as the Fitchburg Line at 8 percent.

4.3.3 Analysis of Impacts

This section presents the social or economic effects from implementing each of the South Coast Rail project alternatives during the construction phase and upon completion of the project. The potential long-term social and economic effects considered include loss of property tax revenue for municipalities from the acquired privately owned parcels, employment displacement, residential displacement, and fragmentation of neighborhoods or loss of continuity between neighborhoods. The indirect and

[28] Ibid.

cumulative socioeconomic effects associated with the South Coast Rail Alternatives are addressed in Chapter 5.

The impact analysis includes: (1) the potential impacts along alternative alignments; (2) the potential impacts at the station locations and; (3) the potential impacts at layover facilities. The land acquisition required for the alignments, stations and layover facilities for each element of the alternatives are presented in Chapter 4.2, *Land Use*. A summary of impacts by alternative is presented in Section 4.3.4.

4.3.3.1 Methodology

Construction Impacts Methodology

The construction associated with the alternatives would support temporary jobs in the South Coast region in construction and related industries during the estimated four-year construction period. Construction job estimates are based on the Corridor Plan,[29] which presents total economic impacts for four study areas: (1) Taunton and communities south; (2) Northern communities; (3) Boston and Cambridge; and (4) the rest of Massachusetts.

The economic impact assessment does not include potential negative effects related to temporary displacement of businesses and their operations or lost economic opportunities during construction activities.

Permanent Impacts Methodology

The potential long-term social and economic effects of the South Coast Rail alternatives include loss of property tax revenue for municipalities from the acquired privately owned parcels, displacement of existing businesses, residential displacement, fragmentation of neighborhoods or loss of continuity between neighborhoods and job creation related to the operation of the new service.

The land acquisition required for the alignments, stations and layover facilities for each element of the alternatives are presented in Chapter 4.2, *Land Use*, which identifies parcel ownership and land usage for each parcel. The right-of-way acquisitions would generally be small portions of numerous undeveloped parcels. Property tax revenue losses associated with the right-of-way acquisitions of small portions of undeveloped parcels were not estimated and it was assumed that there would not be any job displacement or residential displacement associated with these small acquisitions. Exceptions are discussed in the relevant sections.

For privately-owned parcels that would be wholly acquired for the layover facilities or train stations, or where more than 50 percent of the parcel would be acquired, it is assumed that a proportional value of property tax revenue would be lost. Estimates of annual property tax revenue loss (in 2013 dollars) from parcels were made based upon each municipality's property tax formula. Estimates of the loss of property tax revenues for local municipalities, property tax revenue data were obtained based on a review of online resources of the affected municipalities. A screening analysis was performed to identify which parcels have a potential for job displacement based on the presence of privately-owned industrial or commercial buildings. It was assumed that all jobs at risk for displacement would be lost. Residential displacement was estimated by multiplying the number of units that would potentially displaced by the average household size in the affected municipality.

[29] Massachusetts Executive Office of Transportation and Public Works and Massachusetts Office of Housing and Economic Development. South Coast Rail Economic Development and Land Use Corridor Plan. June 2009. Prepared by Goody Clancy: Boston.

Where less than 50 percent of a parcel would be acquired for the layover facilities or train stations, it was assumed that the scale and precision of the preliminary engineering plans limit the accuracy of the acquisition projections. Changes in property tax revenue loss resulting from any remaining minimal acquisitions will be determined in final design of the selected alternative.

The potential social effects of the railroad alignments include neighborhood fragmentation or loss of continuity between neighborhoods. This potential impact was evaluated by reviewing locations where constructing new railroad corridors or reconstructing unused railroads are proposed, in particular focusing on where these alignments pass through residential areas. A qualitative rating of fragmentation effects was made on a relative basis for each alignment, ranging from none to moderate, depending upon the number of road crossings, degree of neighborhood maturity, and housing density along the alignments. Neighborhood fragmentation is not considered a likely effect of improving and using existing, active railroad alignments. It is also not a likely effect of reconstructing or constructing and using non-linear facilities such as stations or layover facilities. More information on the social effects is presented in Chapter 4.5, *Visual and Aesthetic Resources*, where changes in the visual environment that would adversely affect communities are identified.

All Build Alternatives would require employees for train operations, rail or highway maintenance, station and layover facility operations, and administration. Some of these roles may be assigned to existing MBTA staff; others would require new hires or contracts with private firms. The number of new jobs that would be created for these tasks was not estimated.

Property Value Impact Analysis Methodology

Residential property values near stations and alignments may be affected. A literature review[30] of the effects of commuter rail service on property values concluded that residential property values in areas with access to commuter rail increased anywhere from 5 to 25 percent, with most increases between 6 and 10 percent. The literature review findings are presented in more detail below. Presumably, greater increases would be realized closer to the stations, with less of an effect with increasing distance from the station. This indirect effect is considered for the train stations, as these facilities would be access points to the transit system. Each station site was reviewed for nearby properties (within a 0.5-mile radius) zoned for residential use to qualitatively determine if residential property values would be likely to increase. No changes in residential real estate values are expected near existing stations. The potential increases in residential property values are not quantified. A screening analysis indicates the possibility of an increase in residential property values near each station with a “yes” or “no.”

As described in Chapter 4.4, *Environmental Justice*, some station sites are within or near low-income neighborhoods. Increases in property values in these neighborhoods could make homes and businesses too expensive to afford. However, TOD may offset this effect if development plans require affordable housing.

Similarly, residential real estate values in proximity to railroad alignments may decrease in value. Based on an analysis of noise-sensitive receptors (i.e., residents) along the alignments, residential properties that would be affected by construction activities or train operations would likely experience a decrease in real estate value. Residential properties that would be moderately or severely impacted by noise are identified in Chapter 4.6, *Noise*. As with the residential value increases near station sites, residential

[30] Reservitz, David. 2009. Impacts of Commuter Rail Service on Residential Property Values. Reservitz Law Offices: Boston.

value decreases along railroad alignments presumably would be greatest close to the alignments with less of an effect with increasing distance from the railroad.

In summary, residential property values near stations may increase as a result of the improved access to transit, with further increases possible in areas where transit-oriented development (TOD) is possible. Conversely, residential property values along the alternative alignments may decrease as a result of increased noise from train operations. Property value increases may have an adverse impact on certain populations (low income), if homes and businesses become too expensive to afford. This effect may be offset if TOD includes an affordable housing component.

Property Value Impact Literature Review Summary

Reservitz (2009)[31] reviewed several studies on commuter rail impacts to property values, and found that commuter rail access near residential property values has a positive impact anywhere from 5 to 25 percent with most studies concluding that values would increase by 6 to 10 percent.

Armstrong (1994)[32] found that "there is an increase in single-family residential property values of approximately 6.7 percent by virtue of being located within a community having a commuter rail station."

Chen et al. (1997)[33] found that the positive effect on real estate values near station sites (due to increased access to transit services) was partially offset by a negative effect along the rail lines (due to increased nuisance impacts, principally noise and vibration). Chen et al did not quantify either the positive or negative changes in real estate values, but concluded that the "positive effect dominates the negative effect, which implies a declining price gradient as one moves away from [light rail transit] stations for several hundred meters." Armstrong (1994) found that there could be as much as a 20 percent decrease in residential property value for residences within 400 feet of MBTA's Fitchburg line.

4.3.3.2 No Build (Enhanced Bus) Alternative

The No Build Alternative (Enhanced Bus) would improve transit service to Boston from New Bedford, Fall River, and Taunton and would not include any capital improvements. Under this alternative, no new rail or bus service would be provided to Southeastern Massachusetts.

No new construction or land acquisition would be required for the No Build Alternative. There would be no impacts to property tax revenues or jobs. This alternative would not directly affect the social and economic environment.

4.3.3.3 Southern Triangle (Common to all Rail Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to the Stoughton and Whittenton Alternatives. The Southern Triangle would require 7.3 acres of private land acquisition for the diesel alternatives and 8.6 acres for the electric alternatives. Twenty-five privately-owned parcels would be acquired in full or part to support the right-of-way under all Rail Alternatives.

[31] Reservitz, D. Impacts of Commuter Rail Service on Residential Property Values. Reservitz Law Offices: Brockton MA.

[32] Armstrong, R.J. Jr. 1994. Impacts of Commuter Rail Service as Reflected in Single-Family Residential Property Values. In Transportation Research Record No. 1466, pp 88-98. Transportation Research Board of the National Academies.

[33] Chen, H., A. Rufolo, and K.J. Dueker. 1997. Measuring the Impact of Light Rail Systems on Single Family Home Values: A Hedonic Approach with GIS Application. Discussion Paper 97-3. Center for Urban Studies, College of Urban and Public Affairs, Portland State University: Portland OR.

An additional three parcels totaling 1.3 acres would be necessary to support traction power facilities under the electric alternatives. The number, area, public or private ownership, and general land use of parcels that would be acquired in each municipality along the Fall River Secondary and New Bedford Mainline right-of-ways, and for the traction power facilities for the electric alternatives, are summarized in Table 4.2-2 and shown in Figures 4.2-1a-d and 4.2-2a-c in Chapter 4.2, *Land Use*.

Thirteen undeveloped parcels totaling approximately 2.3 acres would be affected to support the Southern Triangle right-of-way or traction power facility sites. No business or community facility displacements would result from acquisition necessary to support the Rail Alternatives in the Southern Triangle. Six industrial parcels totaling 0.6 acre would be affected to support the right-of-way; no industrial parcels would be acquired for traction power facilities.

Three residential displacements would occur on two parcels at Myricks Junction in Berkley (Figure 4.2-2a). Based on the average Berkley household size of 3.1 persons, nine persons would be displaced by these acquisitions. Full acquisition of the two residential parcels in Berkley would result in the estimated property tax loss of approximately of $4,724.88 ($2009). Six partial acquisitions on residential parcels in Fall River and Freetown, and one additional partial acquisition in Berkley would be necessary to support the Southern Triangle right-of-way. Because of the size and anticipated impact on these parcels, property tax revenue loss has not been calculated for these parcels.

Improving and using the existing, active Fall River Secondary and New Bedford Main Line for the South Coast Rail project would not result in neighborhood fragmentation.

4.3.3.4 Stoughton Electric Alternative

The Stoughton Electric Alternative north of the Southern Triangle would be comprised of a portion of the Northeast Corridor and the entire Stoughton Line. This evaluation focuses on the existing and extended Stoughton Line segment; no construction would be required in the Northeast Corridor segment for this alternative, and the Southern Triangle segments were addressed in Section 4.3.3.3.

Along the Stoughton Line segment, the Stoughton Electric Alternative would require a total of 44.7 acres (87 parcels) of privately owned land: 43.6 acres (80 parcels) for the right-of-way, plus an additional 1.1 acres (seven parcels) for traction power facilities. The number, area, public or private ownership, and general land use of parcels that would be acquired in each municipality along the Stoughton Line right-of-way and for the traction power facilities for the Stoughton Electric Alternative, are summarized in Table 4.2-3 and shown in Figures 4.2-3a-e in Chapter 4.2, *Land Use*.

Most of the land that would be acquired for the Stoughton Line right-of-way or traction power facilities consists of small portions of either publicly or privately owned parcels. Many of the affected parcels are undeveloped parcels; other land uses include industrial, commercial and residential. Eight of the privately owned parcels that would be acquired for the Stoughton Line right-of-way would be acquired in full.

Property tax revenue losses for acquisitions of small portions of undeveloped parcels were not estimated. Two parcels in Raynham, near Raynham Junction and along the proposed right-of-way, would be acquired in full. Property tax losses from acquiring these two parcels would be $7,030, in 2013 dollars.

Residential displacement would occur in Raynham, from one home occupying one parcel south of Raynham Junction (Figure 4.2-3d). Based on the average Raynham household size of 2.8 persons, three persons would be displaced by this acquisition. No business or community facility displacements would result from these acquisitions along the Stoughton Line.

Improving and using the existing, active Stoughton Line for the South Coast Rail project would minimally fragment neighborhoods. The active portion of the Stoughton Line terminates at the Stoughton Station; the railroad south of this point ceased operations in the late 1950s. Track has been removed from much of the railroad bed between the Stoughton Station and Weir Junction. Informal and unauthorized residential and recreational use of the railroad bed in several communities has established neighborhood continuity where none may have existed during the active phase of the railroad.

In Stoughton, the alignment parallels Washington Street south of the Stoughton Station, adjacent to or passing through medium density commercial, industrial, and residential areas. The alignment does not bisect any residential areas in this segment and thus no neighborhood fragmentation would result from reconstruction and use of the Stoughton Line.

Entering Easton, the alignment passes through the densely developed downtown area, adjacent to or passing through commercial, industrial, and residential areas. An existing pedestrian-only crossing, at Williams Street near downtown Easton, will be closed, disrupting continuity in this community. In this same area, the adjacent neighborhoods were constructed near the active railroad line but have since encroached into the railroad right-of-way. Yards have been expanded into the right-of-way, and pedestrians have used the right-of-way as an informal path. Re-establishing rail service in this segment may fragment neighborhood relationships that have become informally established during the inactive railroad phase.

South of Easton village, the Stoughton Line corridor passes through low- to moderate-density residential development. Neighborhoods along this segment appear to lack cross-railroad continuity; it is unlikely that reconstructing and using the Stoughton Line in this segment would fragment any neighborhood. Near the southern Easton town boundary (approaching the Hockomock Swamp), the Stoughton Line passes between the Easton Country Club and the Pine Oaks Golf Course, in a narrow corridor separating these two private recreational facilities. The Stoughton Line would not fragment these independent, but similar, entities. Immediately prior to entering the Hockomock Swamp, the Stoughton Line passes the Southeastern Regional Vocational Tech School. Sports fields here have encroached into the Stoughton Line right-of-way, and would need to be relocated. This facility relocation would disrupt sports field use but not fragment the neighborhood.

In Raynham and Taunton, the Stoughton Line again is adjacent to or passes through commercial, industrial, and residential development. The alignment crosses most residential neighborhoods perpendicular to main thoroughfares. Although temporary delays in traffic patterns may occur at road/railroad crossings, it is unlikely that the presence of the railroad in this segment would fragment the neighborhoods or disrupt continuity. An exception would be the Route 138 (Broadway) crossing in Raynham. This crossing would be constructed as grade-separated, avoiding traffic delays during operations.

4.3.3.5 Stoughton Diesel Alternative

The Stoughton Diesel Alternative is identical to the Stoughton Electric Alternative with the exception of the locomotive power source. Diesel-powered train service differs from electric-powered service in not

requiring electrical infrastructure, and thus requiring a smaller footprint. The footprint of the impacted area would be smaller because traction power facilities would not be necessary. Right-of-way parcel acquisitions required for the Stoughton Line portion of the Stoughton Diesel Alternative are presented in Table 4.2-3 and shown in Figures 4.2-3a-e. This segment would require 43.6 acres (80 parcels) of privately owned land.

As with the Stoughton Electric Alternative, no business or community facility displacements would result from these acquisitions along the Stoughton Line. Residential displacement would occur in Raynham, from one home occupying one parcel south of Raynham Junction (Figure 4.2-3d). Based on the average Raynham household size of 2.8 persons, three persons would be displaced by this acquisition. Two parcels in Taunton located south of and adjacent to Thrasher Street, each occupied by a residence, would be acquired in full, resulting in residential displacement.

As discussed above for the Stoughton Electric Alternative, the Stoughton Diesel Alternative may fragment neighborhood relationships that have become informally established during the inactive railroad phase near Easton. Sports fields near the Hockomock Swamp have encroached into the Stoughton Line right-of-way, and would need to be relocated.

4.3.3.6 Whittenton Electric Alternative

The Whittenton Electric Alternative would result in many of the same impacts along the Stoughton Line as the Stoughton Alternatives, except that the southernmost portion of the Stoughton Line (from Raynham Junction to Weir Junction) would not be used. Therefore, residential displacements south of Raynham Junction under the Stoughton Alternatives would be avoided.

Land acquisition requirements along the portion of the Attleboro Secondary of the Whittenton Alternative, as noted in the DEIS/DEIR, have been eliminated (other than those related to the Dana Street Station described separately in Section 4.3.3.8).

For the right-of-way and traction power facilities, the Whittenton Electric Alternative would require 54.4 acres (83 parcels) of privately owned land from the combination of the Whittenton Branch, and the northern portion of the Stoughton Line: 53.3 acres (76 parcels) for the right-of-way and 1.1 acres (7 parcels) for the traction power facilities. Although the former Whittenton Branch segment of the Whittenton Alternative is owned by the Commonwealth, minor acquisitions would be required along the right-of-way to accommodate ancillary structures. The number, area, public or private ownership, and general land use of parcels that would be acquired for the Whittenton Electric Alternative are summarized by municipality in Table 4.2-4 and shown in Figures 4.2-4a-b.

Most of the land that would be acquired for this segment is small portions of undeveloped parcels. Property tax revenue losses for acquisitions of small portions of land were not estimated (i.e., less than 50 percent).

No residential, business, or community facility displacements would result from these small acquisitions.

The Whittenton Branch passes through a range of agricultural, industrial, commercial, and residential areas between Raynham Junction and Whittenton Junction. In Raynham and Taunton, the Whittenton Branch is adjacent to or passes through commercial, industrial, and residential development. The alignment crosses most residential neighborhoods perpendicular to main thoroughfares, or parallels the outer boundary of the neighborhoods. Although temporary delays in traffic patterns may occur at

road/railroad crossings, it is unlikely that the presence of the railroad in this segment would fragment the neighborhoods or disrupt continuity. Access to an aggregate facility adjacent to the Whittenton Branch would be relocated permanently. Current use of the right-of-way as an informal path would cease.

4.3.3.7 Whittenton Diesel Alternative

The Whittenton Diesel Alternative is identical to the Whittenton Electric Alternative with the exception of the locomotive power source. Diesel-powered train service differs from electric-powered service in not requiring electrical infrastructure, and thus requires a smaller footprint. In the Southern Triangle and along the Stoughton Line (north of Raynham Junction only), the land acquisition impacts of the Whittenton Diesel Alternative would be the same as described for the Stoughton Diesel Alternative. Along the Whittenton Branch, impacts of the Whittenton Diesel Alternative are anticipated to be a similar negligible amount as with the Whittenton Electric Alternative.

As with the Whittenton Electric Alternative, most of the land that would be acquired for this segment consists of small portions of undeveloped parcels. Property tax revenue losses for small acquisitions were not estimated (i.e., less than 50 percent). No residential, business, or community facility displacements would result from these small acquisitions. Neighborhood fragmentation impacts are also the same as for the Whittenton Electric Alternative.

4.3.3.8 Stations

This section provides basic descriptions of each station and a list of the parcels to be acquired, in whole or in part, to construct or reconstruct these stations for the South Coast Rail project. For the privately owned parcels that would be wholly acquired for the train stations, or where more than 50 percent of the parcel would be acquired, it is assumed that a proportional value of property tax revenue would be lost. Estimates of annual (in 2013 dollars) property tax revenue loss from parcels were made based upon each municipality’s property tax formula. A screening analysis was performed to identify which parcels have a potential for job displacement based on the presence of privately-owned industrial or commercial buildings. It was assumed that all jobs at risk for displacement would be lost. Residential displacement was estimated by multiplying the number of units that would potentially displaced by the average household size in the affected municipality. This evaluation does not consider neighborhood fragmentation, as the stations would not be linear facilities dividing communities.

Southern Triangle (Common to all Rail Alternatives)

The Southern Triangle would include six stations which are all common to all Build Alternatives.

Fall River Depot Station

The Fall River Depot Station would be a new station constructed along the Fall River Secondary to serve all Build Alternatives. It would be located near the intersection of North Davol Street and Pearce Street in Fall River.

The Fall River Depot Station site is a previously developed parcel including and surrounded by commercial and industrial development. Parcels that would be acquired and converted to transportation/utilities land use to construct the Fall River Depot Station are listed in Table 4.3-10 and shown in Figure 4.2-28.

The Fall River Depot Station would require 5.11 acres of land, comprised of 4.94 acres (16 parcels) of privately owned land and 0.17 acre (one parcel) of publicly owned land. Business displacements would result from these acquisitions. Commercial or industrial buildings on five of the parcels listed above would be acquired to construct this station. Businesses present include a flooring store, electrical company, tire service shop, and automobile detail service. Job losses from businesses occupying these buildings would be expected. Land acquisition for the Fall River Depot Station would not displace any community facilities, but would result in residential displacement (Parcel 0-22-0006). Based on the Fall River average household size of 2.3 persons, approximately 2 residents would be displaced.

All privately owned parcels would be acquired in whole or in excess of 50 percent;[34] property tax revenue losses for the City of Fall River are estimated at $70,777 per year, in 2013 dollars. Parcel number O-15-0020 is owned by the City of Fall River; no property tax revenue loss would result from acquiring this parcel.

Table 4.3-10 Fall River Depot Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
O-15-0001	Private	Industrial	Industrial	$7,836	Yes	0.80	100
O-15-0002	Private	Industrial	Industrial	$8,151	No	0.32	100
O-15-0008	Private	Industrial	Industrial	$11,830	Yes	0.19	100
O-15-0009	Private	Commercial	Industrial	NA[1]	Yes	0.07	100
O-15-0010	Private	Industrial	Commercial	NA[1]	Yes	0.12	100
O-15-0018	Private	Industrial	Industrial	$7,434	No	1.52	100
O-15-0020	Public	Industrial	Industrial	NA	No	0.17	100
O-15-0031	Private	Industrial	Undeveloped	$338	No	0.03	100
O-15-0032	Private	Industrial	Industrial	$3,200	No	0.35	100
O-15-0034	Private	Industrial	Industrial	$410	No	0.04	100
O-22-0005	Private	Commercial	Commercial	$5,803	Yes	0.12	100
O-22-0006	Private	Residential	Residential	$7,248	No	0.10	100
O-22-0007	Private	Residential	Commercial	$9,336	Yes	0.12	100
O-22-0008	Private	Commercial	Commercial	$1,625	Yes	0.53	100
O-22-0011	Private	Commercial	Industrial	$4,516	Yes	0.47	100
O-22-0016	Private	Commercial	Commercial	$3,050	No	0.12	100
O-22-0017	Private	Commercial	Commercial	NA[2]	Yes	0.04	100
TOTAL				**$70,777**		**5.11**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
1 Parcels O-15-0009 and O-15-0010 are included with Parcel O-15-0008 in Fall River assessor records.
2 Parcel O-22-0017 is included with Parcel O-22-0005 in Fall River assessor records.

Freetown Station

The Freetown Station would be a new station constructed along the Fall River Secondary to serve all Build Alternatives. It would be located along South Main Street in Freetown.

[34] Whenever more than 50 percent of a parcel is acquired, it is assumed that the entire parcel is acquired, resulting in a 100% loss of tax revenue

The Freetown Station site is an undeveloped parcel surrounded by low density residential development and undeveloped land. The parcel that would be acquired and converted to transportation/utilities land use to construct the Freetown Station is listed in Table 4.3-11 below and shown in Figure 4.2-29.

The Freetown Station would require acquisition of 4.18 acres (one parcel) of privately-owned land. No residential, business, or community facility displacements would result from this acquisition for the Freetown Station.

Less than 50 percent of parcel number 233-19 would be acquired for the Freetown Station and, accordingly, property tax revenue losses were not determined.

Table 4.3-11 Freetown Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
233-19	Private	Commercial	Undeveloped	TBD	No	4.18	15

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
TBD To be determined.

King's Highway Station

The King's Highway Station would be a new station constructed along the New Bedford Main Line to serve all Build Alternatives. It would be located near the intersection of King's Highway and Tarkiln Hill Road in New Bedford.

The King's Highway Station site is a previously developed parcel surrounded by industrial development. This station would share a parking lot with adjacent businesses; no land acquisition would be required (Figure 4.2-30). There would be no direct effects to land uses or the social and economic environment at this location.

Whale's Tooth Station

The Whale's Tooth Station would be a new station constructed along the New Bedford Main Line to serve all Build Alternatives. It would be located near the intersection of Acushnet Avenue and Hillman Street, near the southern terminus of the New Bedford Main Line.

The Whale's Tooth Station site is a previously developed parcel surrounded by industrial development. The City of New Bedford recently constructed a parking lot at this site in anticipation of the proposed South Coast Rail project. Development of this station would not require land acquisition. There would be no direct effects to land uses or the social and economic environment at this location.

Battleship Cove Station

The Battleship Cove Station would be a new station constructed along the Fall River Secondary that would serve all Build Alternatives. It would be located on Water Street in Fall River, near the southern terminus of the Fall River Secondary.

The Battleship Cove Station site is a previously developed parcel that is within the Ponta Delgada Plaza.

Construction of this station would not require land acquisition; would not result in any business, residential or community facility displacements; and would not result in direct impacts to land use or the social or economic and economic environment.

Taunton Depot Station

The Taunton Depot Station would be a new train station constructed along the New Bedford Main Line that would serve all rail alternatives. It would be located at 872 County Street in Taunton, behind the existing Target plaza.

The Taunton Depot Station site is an undeveloped parcel adjacent to commercial development and undeveloped lands. Parcels that would be acquired and converted to transportation/utilities land use to construct the Taunton Depot Station are listed in Table 4.3-12 below and shown in Figure 4.2-35.

Table 4.3-12 Taunton Depot Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
107-47	Private	Residential	Commercial	$106	No	0.56	100.0
107-48	Private	Industrial	Undeveloped	TBD	No	10.97	40
TOTAL				**$106**		**11.53**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
TBD To be determined.

The Taunton Depot Station would require 11.53 acres (two parcels) of privately-owned land. No residential, business, or community facility displacements would result from these acquisitions for the Taunton Depot Station.

Parcel number 107-47 would be wholly acquired and more than 50 percent of parcel number 107-48 would be acquired; property tax revenue losses for the Town of Taunton are estimated at $106 per year, in 2013 dollars. Less than 50 percent of parcel number 107-57 would be acquired for the Taunton Depot Station and, accordingly, property tax revenue losses were not determined. Additional property tax revenue losses could result from this acquisition.

Stoughton and Whittenton Alternatives

The same stations would be reconstructed or newly constructed under the Stoughton and Whittenton Alternatives, with the exception of one. More specifically, in addition to the stations common to all Build Alternatives, reconstruction of one existing station along the Stoughton Line (Canton Center) and construction of four new train stations (Stoughton, Easton Village, North Easton and Raynham Park) would occur under the Stoughton Alternatives and the Whittenton Alternatives. The Taunton Station would only be constructed under the Stoughton Alternatives while the Dana Street Station would be built only under the Whittenton Alternatives.

Canton Center Station

The Canton Center Station is an existing train station along the Stoughton Line that would be reconstructed and would serve all Build Alternatives. It is located at 710 Washington Street in Canton. No land acquisition would be required for reconstructing the Canton Center Station (Figure 4.2-25). There would be no direct effects to land uses or the social and economic environment at this location.

Canton Junction Station

The Canton Junction Station is an existing train station at the junction of the Stoughton Line with the Northeast Corridor; it would serve all Build Alternatives. It is located at the intersection of Beaumont and Sherman Streets in Canton. No construction or land acquisition would be required at the Canton Junction Station (Figure 4.2-26). There would be no direct effects to land uses or the social and economic environment at this location.

Easton Village Station

The Easton Village Station would be a new train station constructed along the Stoughton Line that would serve all Build Alternatives. The Easton Village Station site is on Sullivan Avenue at the transition point to Mechanic Street (near the intersection with Pond Street) in Easton.

The Easton Village Station site is an undeveloped parcel surrounded by industrial and residential development. The land is currently used as a parking lot. Parcels that would be acquired and converted to transportation/utilities land use to construct the Easton Village Station are listed in Table 4.3-13 and shown in Figure 4.2-27.

Table 4.3-13 Easton Village Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
16U-129	Private	Industrial	Commercial	TBD	No	0.11	13.5
16U-129C	Private	Industrial	Commercial	TBD	No	0.12	1.4
TOTAL				**TBD**		**0.23**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
TBD To be determined.

The Easton Village Station would require 0.23 acre (two parcels) of privately-owned land. No residential, business, or community facility displacements would result from these acquisitions for the Easton Village Station. Less than 50 percent of parcel numbers 16U-129 and 16U-129C would be acquired for the Easton Village Station and, accordingly, property tax revenue losses were not determined.

North Easton Station

The North Easton Station would be a new train station constructed along the Stoughton Line that would serve all Build Alternatives. It would be located at 21 Washington Street in Stoughton, behind the Roche Brothers Plaza.

The North Easton Station site is an undeveloped parcel surrounded by commercial development. Parcels that would be acquired and converted to transportation/utilities land use to construct the North Easton Station are listed in Table 4.3-14 and shown in Figure 4.2-45.

The North Easton Station would require 10.24 acres (five parcels) of privately-owned land. No residential, business, or community facility displacements would result from these acquisitions for the North Easton Station.

More than 50 percent of parcel number 060-006 would be acquired; property tax revenue losses for the Town of Easton are estimated at $6,893 per year, in 2013 dollars. Less than 50 percent of parcel

numbers 1U-1, 1U-48, 060-008 and 060-009 would be acquired. Property tax revenue losses were not estimated for these minor acquisitions.

Table 4.3-14 North Easton Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
1U-1	Private	Residential	Undeveloped	TBD	No	1.65	8
1U-48	Private	Commercial	Undeveloped	TBD	No	1.00	27
060-006	Private	Commercial	Undeveloped	$6,893	No	6.31	100
060-008	Private	Commercial	Commercial	TBD	No	0.59	15
060-009	Private	Commercial	Commercial	TBD	No	0.69	20
TOTAL				**$6,893**		**10.24**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
TBD To be determined.

Raynham Park Station

The Raynham Park Station would be a new train station constructed along the Stoughton Line that would serve the Stoughton or Whittenton Alternatives. It would be located at 1958 Broadway in Raynham, at the former Raynham Park Greyhound Track, currently the Raynham Park Simulcast Center.

The Raynham Park Station site is a developed parcel surrounded by recreational development and undeveloped land. Parcels that would be acquired and converted to transportation/utilities land use to construct this station are listed in Table 4.3-15 below and shown in Figure 4.2-32.

Table 4.3-15 Raynham Park Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
1-15	Private		Commercial	TBD	No	3.09	34
1-19-1	Private		Commercial	$7,030	Yes	8.81	59
TOTAL				**$7,030**		**11.90**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
TBD To be determined.

The Raynham Park Station would require 11.90 acres (two parcels) of privately owned land. Commercial buildings on parcel number 1-19-1 would be acquired to construct this station. The business present on this parcel is the Raynham Park Simulcast Center (an off-track betting facility). A proposal for developing a slots parlor casino on the Simulcast Center property exists at the time of the preparation of the FEIS/FEIR, but the outcome of this proposal is uncertain as there is a competitive process to determine the location of the new casino.[35] This assessment assumes that the land acquisition would result in the displacement of one business and job loss. No residential or community facility displacements would result from these acquisitions.

[35] http://www.bostonglobe.com/metro/2013/06/11/raynham-park-strikes-deal-with-town-over-slot-machine-parlor/1QLjMn7wbBFwoq505pvoeL/story.html.

More than 50 percent of parcel number 1-19-1 would be acquired; property tax revenue losses for the Town of Raynham are estimated at $7,030 per year, in 2013 dollars. Less than 50 percent of parcel number 1-15 would be acquired and, accordingly, property tax revenue losses were not determined.

Stoughton Station

The Stoughton Station would be a new train station along the Stoughton Line that would serve all Build Alternatives. In order to accommodate a second track, the existing Stoughton Station would be shifted from its location between Porter and Wyman Streets to a new location south of the Wyman Street at-grade crossing. Land uses and zoning designations of the parcel that would be acquired and converted to transportation/utilities land use to reconstruct the Stoughton Station are listed in Table 4.3-16 below and shown in Figure 4.2-33.

Table 4.3-16 Stoughton Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
053-101	Private	Industrial	Industrial	$7,923	Yes	1.05	100
053-102	Private	Industrial	Commercial	$8,782	Yes	4.42	100
054-110	Private	Commercial	Commercial	TBD	No	0.04	2
054-401	Private	Commercial	Commercial	TBD	No	0.01	10
054-406	Private	Industrial	Industrial	$4,436	Yes	1.90	100
054-407	Private	Industrial	Undeveloped	$1,352	No	0.02	100
TOTAL				**$22,493**		**7.44**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various)
TBD To be determined.

The relocated Stoughton Station would require acquisition of 7.44 acres (six parcels) of privately owned land. Four parcels would be obtained in entirety; 10 percent or less of two other parcels would be acquired. The estimated annual property tax revenue losses for the Town of Stoughton would be $24,493.

Although no residential or community facility displacements would result from these acquisitions, business displacements would occur and job losses may result. Parcels 053-101 and 053-102 are owned by individuals associated with the Alpha Chemical Company that has a manufacturing facility on Morton Street adjacent to the northern boundary of the station site. Available data indicate that these two parcels are used as warehouses and office (conference) space. Parcel 054-406 is owned by the Murphy Coal Company, a business with offices nearby on Washington Street. Available data indicate that the parcel contains a fuel storage and materials handling yard, parking lot, and vehicle repair garage.

The proposed relocation of the Stoughton Station would open up 2.5 acres of land for potential redevelopment. MBTA owns this property and it would be released for sale and redevelopment. This land, currently occupied by tracks and parking areas, is on the east side of the proposed tracks.

Taunton Station (Stoughton Alternatives)

The Taunton Station would be a new train station constructed along the Stoughton Line that would serve the Stoughton Alternatives only. It would be located near the intersection of East Arlington Street and William Hooke Lane in Taunton.

The Taunton Station site is a previously developed parcel surrounded by commercial development. Parcels that would be acquired and converted to transportation/utilities land use to construct the Taunton Station are listed in Table 4.3-17 below and shown in Figure 4.2-34.

Table 4.3-17 Taunton Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
55-759	Private	Residential	Commercial	$2,059	No	1.53	100
55-760	Private	Industrial	Undeveloped	$6,422	No	7.44	100
55-761	Private	Industrial	Undeveloped	$2,107	No	0.51	100
55-762	Private	Industrial	Undeveloped	$749	No	0.50	100
55-763	Private	Industrial	Undeveloped	$2,242	No	0.25	100
55-764	Private	Industrial	Undeveloped	$1,407	No	0.64	100
Pub ROW	Public	Transportation	Transportation	NA	No	0.95	100
TOTAL				**$14,986**		**11.82**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
NA Not applicable.

The Taunton Station would require 11.82 acres of land, comprised of 10.87 acres (six parcels) of privately owned land and 0.95 acre (one parcel) of publicly owned land. No residential, business, or community facility displacements would result from these acquisitions for Taunton Station.

More than 50 percent of all of the privately owned parcels would be acquired; property tax revenue losses for the Town of Taunton are estimated at $14,986 per year, in 2013 dollars. The public parcel is owned by the Town of Taunton; no property tax revenue loss would result from this acquisition.

Dana Street Station (Whittenton Alternatives)

The Dana Street Station would be a new station constructed along the Attleboro Secondary that would serve the Whittenton Alternatives only. It would be located just south of the Danforth Street grade crossing, within walking distance of downtown Taunton. This area is densely developed with land uses including commercial, industrial, and residential properties.

The Dana Street Station site in Taunton is currently a vacant lot. The parcels that would be acquired and converted to transportation/utilities land use to construct this station are listed in Table 4.3-18 and shown in Figure 4.2-40.

The Dana Street Station in would require acquisition of 4.09 acres encompassing nine parcels of privately owned land. These parcels are vacant or appear to have an industrial use, but most are zoned as residential properties. More than 50 percent of parcel numbers 54-558, 54-449, 54-450, 54-451, 54-452, 54-453, 54-454 and 54-455 would be acquired; property tax revenue losses for the Town of Taunton are estimated at $6,112 per year, in 2013 dollars. Less than 50 percent of parcel number 54-171 would be acquired; property tax revenue losses were not determined. No residential, business, or community facility displacements would result from this acquisition for the Dana Street Station.

Table 4.3-18 Dana Street Station: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
54-171	Private	Industrial	Industrial	TBD	No	0.56	49
54-448	Private	Residential	Industrial	$1,183	No	0.44	100
54-449	Private	Residential	Industrial	$1,190	No	0.45	100
54-450	Private	Residential	Industrial	$1,203	No	0.47	100
54-451	Private	Residential	Industrial	$1,210	No	0.48	100
54-452	Private	Residential	Industrial	$1,223	No	0.50	100
54-453	Private	Residential	Industrial	$37	No	0.49	100
54-454	Private	Residential	Industrial	$33	No	0.35	100
54-455	Private	Residential	Industrial	$33	No	0.35	100
TOTAL				**$6,112**		**4.09**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
TBD To be determined.

Summary of Effects Associated with Stations

Constructing some of the stations would require removing commercial or industrial buildings, potentially resulting in a loss of jobs. Table 4.3-20 lists the communities where South Coast Rail stations would be sited, the workforce in each community, and whether or not job losses are expected from station construction.

Job loss and business displacement would be limited to Fall River, Raynham and Stoughton. Nine parcels in Fall River, one parcel in Raynham and three parcels in Stoughton would be affected by job displacement and associated job loss. The actual numbers of jobs that would be lost from each of these businesses is not known, but it is expected to be negligible in comparison to the number of workers present in these communities. As shown in Table 4.3-19, the work force in Fall River is estimated to be 36,989, while the Raynham and Stoughton work forces are estimated to be 8,788 and 14,523, respectively.

Table 4.3-19 Workforce in Communities with Stations

Municipality	Workforce	Station	Job Loss
Canton	21,372	Canton Center	No
		Canton Junction	No
Easton	12,627	North Easton	No
		Easton Village	No
Fall River	36,989	Battleship Cove	No
		Fall River Depot	**Yes**
Freetown	3,757	Freetown	No
New Bedford	37,223	King's Highway	No
		Whale's Tooth	No
Raynham	8,788	**Raynham Park**	**Yes**
Stoughton	14,523	**Stoughton**	**Yes**
Taunton	25,653	Taunton	No
		Dana Street	No
		Taunton Depot	No

Source: Metropolitan Area Planning Council (MAPC) *MAPC Projections 013106* (2010 employment projections for Canton, Sharon, and Stoughton) South Coast Regional Planning and Economic Development District (SRPEDD) *Community Quickstats* (summer 2007 employment estimates for all other communities)

4.3.3.9 Layover Facilities

Two overnight layover facilities are planned for the Southern Triangle: one each at or near the end of the Fall River Secondary and the New Bedford Main Line. The Wamsutta site was selected as the preferred layover facility for the New Bedford Main Line and Weaver's Cove East site was selected for the Fall River Secondary. This section provides basic descriptions of each layover facility site and a list of the parcels to be acquired, in whole or in part, to construct these facilities for the South Coast Rail project. This evaluation does not consider neighborhood fragmentation, as the layover facilities would not be linear facilities dividing communities.

Wamsutta

The Wamsutta site layover facility would be constructed along the New Bedford Main Line and would serve all Build Alternatives. It would be located in New Bedford near the intersection of Wamsutta Street and Herman Melville Boulevard, near the southern terminus of the New Bedford Main Line, just north of the Whale's Tooth Station.

The Wamsutta site layover facility alternative location is a previously developed site, currently used as a rail yard for CSX, within an industrial area. The layover facility at the Wamsutta site would require acquisition of 5.90 acres (one parcel) of publicly owned land. The parcel that would be acquired to construct this layover facility is listed in Table 4.3-20 and shown in Figure 4.2-37.

Table 4.3-20 Layover Facility at the Wamsutta Site: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
72-275	Public	Industrial	Undeveloped	N/A	No	5.90	54

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

No residential, business, or community facility displacements would result from this acquisition for the Wamsutta site.

Parcel number 72-275 is owned by Housing 70 Corporation (the City of New Bedford); no property tax revenue loss would result from acquiring this parcel.

Weaver's Cove East

The Weaver's Cove East site layover facility would be constructed along the Fall River Secondary and would serve all Build Alternatives. It would be located in Fall River west of Main Street between the existing Fall River Secondary and Main Street, approximately 2.5 miles from the southern terminus of the Fall River Secondary.

Currently vacant land, a portion of the Weaver's Cove East site was previously developed. Approximately one-half of the site is cleared of vegetation or includes remnant building foundations; the remainder of the site is vegetated. Surrounding land to the north, east, and south is residential; industrial land use is present to the southwest. Undeveloped land is immediately west of the site, adjoining the Taunton River. The parcels that would be acquired to construct a layover facility at the Weaver's Cove East site are listed in Table 4.3-21 below and shown in Figure 4.2-38.

Table 4.3-21 Layover Facility at the Weaver's Cove East Site: Land Acquisition

Parcel Number	Ownership	Generalized Zoning	General Land Use	Property Tax Revenue Loss	Job Loss	Area (acres)	Percent Acquisition
T-15-33[1]	Private	Industrial	Undeveloped	$16,900	No	13.80	90.0
T-1-38	Private	Industrial	Undeveloped	$46,311	No	4.63	100.0
TOTAL				**$63,211**		**18.43**	

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
Note: Additional property tax revenue losses may result from small and/or partial acquisitions that cannot be determined at this phase.
1 Parcel T-15-33 incorporates Parcel T-15-1 in the City of Fall River Assessor's records. Figure 4.2-38 depicts both parcels.

The layover facility at the Weaver's Cove East site would require 18.43acres (two parcels) of privately owned land. No residential, business, or community facility displacements would result from these acquisitions for the Weaver's Cove East site.

Parcel number T-1-38 would be wholly acquired and parcel number T-15-38 would be nearly wholly acquired; property tax revenue losses for the City of Fall River are estimated at $63,211 per year, in 2013 dollars.

Summary of Effects Associated with Layover Facility

Tax effects of the layover site alternatives are listed in Table 4.3-22. The Wamsutta Layover facility would result in no tax losses in New Bedford, while tax losses in Fall River resulting from the Weaver's Cove Layover Facility would be $63,211.

Table 4.3-22 Summary of Layover Facility Potential Effects to the Social and Economic Environment

Candidate Layover Facility Site	Property Tax Revenue Loss	Job Loss	Neighborhood Fragmentation	Residential Property Value Increase
Wamsutta Site	N/A	No	NA	NA
Weaver's Cove East Site	$63,211	No	NA	NA

NA Not applicable

4.3.3.10 Temporary Construction Impacts

The construction associated with the proposed project would support temporary jobs in the South Coast region in construction and related industries during the estimated four-year construction period. Construction job estimates are based on the Corridor Plan, which presents total economic impacts for four study areas: (1) Taunton and communities south; (2) Northern communities; (3) Boston Cambridge; and (4) rest of Massachusetts.

Based upon the preliminary estimates of construction costs, the Corridor Plan suggests that "the total direct, indirect and induced economic effects within the Commonwealth of Massachusetts of the rail alternatives would include about $1.4 billion to $1.8 billion in business output, which would in turn generate 6,800 to 7,800 person-year jobs, and $314 to $360 million in household income."

Delays would likely occur during construction activities and access to businesses could be temporarily affected. Coordination to keep local governments and business owners apprised of construction plans would serve to minimize temporary construction disruptions to business access.

4.3.4 Summary

This section summarizes the effects to the social and economic environment potentially resulting from implementing each of the South Coast Rail project alternatives, based upon preliminary engineering plans. The summaries of parcel acquisition and potentially resulting property tax revenue loss and job loss focus on privately owned parcels, as acquisition of publicly owned parcels would not impact these aspects of the social and economic environment.

4.3.4.1 Stoughton Electric Alternative

By Element

The Stoughton Electric Alternative would be comprised of the elements listed in Table 4.3-23, which also summarize the potential impacts to land uses and the social and economic environment, respectively, that may result from implementing this alternative.

Property tax revenue losses as a result of the Stoughton Electric Alternative are estimated at $197,251 per year, in 2013 dollars; additional property tax revenue losses may result from small and/or partial acquisitions.

Four residences would be displaced. Based on average household size in the affected communities, nine persons would be relocated. Six businesses would be displaced by the Stoughton Electric Alternative. Job losses are expected from business displacements resulting from acquisition of privately owned commercial buildings.

Based on a review of residential and commercial property availability,[36] communities that would be impacted by residential displacements or business displacements have sufficient real estate capacity to absorb these displacements. Affected property owners would be provided compensation/relocation assistance in accordance with federal and state requirements.

Table 4.3-23 Stoughton Electric Alternative: Summary of Potential Effects to the Social and Economic Environment

Element/Component	Property Tax Revenue Loss	Neighborhood Fragmentation	Residential Displacement (homes)	Business Displacement	Job Loss
Railroad Alignments					
Northeast Corridor	-	None	-	-	No
Stoughton Line	$7,030	Moderate	1	-	No
Fall River Secondary	$4,725	None	3	-	No
New Bedford Main	TBD	None	-	-	No
Stations					
Canton Junction	-	NA	-	-	No
Canton Center	-	NA	-	-	No
Stoughton	$22,493	NA	-	2	Yes
North Easton	$6,893	NA	-	-	No
Easton Village	TBD	NA	-	-	No
Raynham Park	$7,030	NA	-	-	No
Taunton	$14,986	NA	-	-	No
Taunton Depot	$106	NA	-	-	No
Freetown	TBD	NA	-	-	No
Fall River Depot	$70,777	NA	-	4	Yes
Battleship Cove	-	NA	-	-	No
King's Highway	-	NA	-	-	No
Whale's Tooth	-	NA	-	-	No
Layover Facilities					
Wamsutta	-	NA	-	-	No
Weaver's Cove East	$63,211	NA	-	-	No
TOTAL/SUMMARY	**$197,251**	**Moderate**	**4**	**6**	**Yes**

TBD To be determined.
NA Not applicable.
Note: Additional property tax revenue losses may result from small and/or partial acquisitions

Moderate neighborhood fragmentation is expected to result from implementation of this alternative. Along the inactive portion of the Stoughton Line, some residential and commercial activity encroachment into the right-of-way has occurred in Stoughton, Easton, Taunton, and Raynham. The railroad has been out of service for some 50 years between Stoughton Station and Raynham Junction, and nearly 100 years between Raynham Junction and Longmeadow Street in Taunton. Over time, some

[36] Online research of residential real estate property availability conducted by reviewing current listings of similar homes (based on zoning of affected properties) in the affected communities at www.realtor.com. Commercial real estate vacancy rates conducted by telephone inquiries to chambers of commerce in the affected communities.

neighborhoods on either side of the alignment have developed continuity across the inactive railroad bed as residents have used the alignment for pedestrian transit to neighbors or commercial districts within walking distance. Re-establishing rail service would include safety fencing along the railroad right-of-way through high-density residential and commercial districts, preventing such informal use of the railroad bed as a path. Additionally, motorists, pedestrians, and bicyclists would be temporarily delayed at at-grade railroad crossings when trains pass, potentially disrupting car-based transit between neighborhoods.

By Municipality

Table 4.3-24 summarizes the private property acquisitions for rights-of-way, stations and layover facilities, as well as annual property tax revenue losses and job losses for each affected municipality that would result from the parcel acquisitions in excess of 50 percent for the Stoughton Electric Alternative. Most acquisitions associated with rights-of-way and traction power facilities are not estimated.

Table 4.3-24 Stoughton Electric Alternative: Property Tax Revenue and Job Losses for Affected Municipalities

Municipality	Component	Private Property Acquisition Area (acres)	Property Tax Revenue Loss[1]	Job Loss
Canton	Canton Center	-	-	No
Easton	North Easton	10.24	$6,893	No
Fall River	Battleship Cove	-	-	No
	Fall River Depot	5.11	$70,777	Yes
	Weaver's Cove East	18.43	$63,211	No
Freetown	Freetown	4.18	TBD	No
New Bedford	Whale's Tooth	-	-	No
	Wamsutta	5.90	-	No
Raynham	Raynham Park	11.90	$7,030	Yes
Stoughton	Stoughton	7.44	$22,493	Yes
Taunton	Taunton	11.82	$14,986	No
	Taunton Depot	11.53	$106	No

TBD To be determined.
Note: Additional property tax revenue losses may result from small and/or partial acquisitions.

4.3.4.2 Stoughton Diesel Alternative

The Stoughton Diesel Alternative would be comprised of the same elements as the Stoughton Electric Alternative as listed above, but would not need electrical infrastructure. The property acquisitions needed for the Stoughton Diesel Alternative are therefore 1.1 acres smaller than for the Stoughton Electric Alternative. The other effects to the social and economic environment that would result from the Stoughton Diesel Alternative (such as property acquisitions for stations, layover facilities, right-of-way, property tax revenue loss, residential and business displacements) are identical to those that would result from the Stoughton Electric Alternative, as provided in Tables 4.3-23 and 4.3-24.

4.3.4.3 Whittenton Electric Alternative

By Element

The Whittenton Electric Alternative (Figure 1.4-3) would be comprised of the elements listed in Table 4.3-25, which also summarize the land acquisition requirements and potential impacts to the social and economic environment, respectively, that may result from implementing this alternative.

Property tax revenue losses as a result of the Whittenton Electric Alternative are estimated at $181,351 per year, in 2013 dollars; additional property tax revenue losses may result from small and/or partial acquisitions that were not estimated.

Three residences would be displaced by the Whittenton Electric Alternative, for the Fall River Secondary right-of-way acquisition at Myricks Junction. Based on average household size in the Berkley, nine persons would be relocated. Four businesses would also be displaced by the Whittenton Electric Alternative for the Fall River Depot Station, and two potential business displacements would result from development of the new Stoughton Station. Job losses are expected from business displacements resulting from acquisition of privately owned commercial buildings, but are not quantifiable at this time.

Based on a review of residential and commercial property availability,[37] communities that would be impacted by residential displacements or business displacements have sufficient real estate capacity to absorb these displacements. Affected property owners would be provided compensation/relocation assistance in accordance with federal and state requirements.

Moderate neighborhood fragmentation is expected to result from implementation of this alternative. Neighborhood fragmentation within the Stoughton Line portion would be as described in the Operations Impacts section. The inactive Whittenton Branch has been out of service for some 50 years. However, neighborhoods on either side of the alignment do not appear to have developed substantive continuity across the inactive railroad bed, partially due to the industrial nature of parcels on either side of the corridor, and partially because portions of the corridor in residential areas are located in a cut section with steep-sided banks, wherein disposal of yard waste and other refuse (rather than pathways to promote neighborhood continuity) has been the primary use of the embankment. Motorists, pedestrians, and bicyclists would be temporarily delayed at at-grade railroad crossings when trains pass, but this effect is not expected to impact continuity among neighborhoods along the Whittenton Branch.

By Municipality

Table 4.3-26 summarizes the private property acquisitions for rights-of-way and stations, annual property tax revenue losses, and job losses for each affected municipality that would result from the parcel acquisitions in excess of 50 percent for the Whittenton Electric Alternative.

[37] Online research of residential real estate property availability conducted by reviewing current listings of similar homes (based on zoning of affected properties) in the affected communities at www.realtor.com. Commercial real estate vacancy rates conducted by telephone inquiries to chambers of commerce in the affected communities.

Taunton	Dana Street	4.09	$6,112	No
	Taunton Depot	11.53	$106	No

TBD To be determined.
Note: Additional property tax revenue losses may result from small and/or partial acquisitions.

4.3.4.4 Whittenton Diesel Alternative

The Whittenton Diesel Alternative would be comprised of the same elements as the Whittenton Electric Alternative as listed above but would not need electrical infrastructure. The area needed for the Whittenton Diesel Alternative is therefore somewhat smaller than for the Whittenton Electric Alternative. The other effects to the social and economic environment that would result from the Whittenton Diesel Alternative are identical to those that would result from the Whittenton Electric Alternative, as provided in Tables 4.3-25 and 4.3-26.

4.3.4.5 Summary Comparison

Table 4.3-27 provides a summary comparison of socioeconomic impacts by community. Also included in Table 4.3-27 are estimated fiscal year 2009 tax levies for each municipality, to allow for comparison of the estimated property value loss to the total tax revenues. For most communities, the anticipated property tax revenue loss is on the order of 0.02 percent, although Fall River would experience up to 0.2 percent loss of property tax revenue. The size of the property tax revenue losses are not expected to put substantial upward pressure on local tax rates and these impacts would be at least partially offset by additional tax revenue associated with economic development/redevelopment in the vicinity of the proposed stations as outlined in the Corridor Plan, as discussed further below.

Table 4.3-27 Comparison of Social and Economic Effects to Municipalities, by Alternative

Municipality	Stoughton Alternatives	Whittenton Alternatives
Canton		
Private Property Acquisition (acres)	-	-
Property Tax Revenue Loss	-	-
Total Canton Tax Levy, 2009: $50,759, 822		
Percent Loss	0	0
Direct Job Loss	No	No
Easton		
Private Property Acquisition (acres)	10.24	10.24
Property Tax Revenue Loss	$6,893	$6,893

Private Property Acquisition (acres)	7.44	7.44
Property Tax Revenue Loss	$22,493	$22,493
Total Stoughton Tax Levy, 2009:		

Municipality	Stoughton Alternatives	Whittenton Alternatives
$44,788,089		
Percent Loss	0.05	0.05
Direct Job Loss	No	No
Taunton		
Private Property Acquisition (acres)	23.35	15.91
Property Tax Revenue Loss	$15,092	$21,098
Total Taunton Tax Levy, 2009: $63,756,063		
Percent Loss	0.02	0.03
Direct Job Loss	No	No

Tax Revenue Impacts

The Corridor Plan graphically presents per-capita property tax receipts for selected South Coast communities in 2006.[38] These data indicate that tax receipts for communities that currently do not have train service (such as Fall River, New Bedford, and Taunton) are lower than for communities that currently do have train service (such as Attleboro, Foxborough, and Sharon). The effects of the current (2009) economic downturn on tax revenues at the municipal level are unknown at this time, nor is it possible to predict tax revenues at the municipal or state levels in 2030 with any precision.

The direct property tax revenue losses for affected communities would be insignificant as compared to the total property tax receipts for each town. Property acquisitions (converting privately owned parcels to publicly owned, thereby eliminating the property tax generated) would be minimal, and few business or residential displacements would result from any of the alternatives.

Indirectly, property values are expected to increase near station sites due to increased access to transit but decrease along the rail alternative alignments due to increased noise levels from train operations. It is assumed that residential property values would increase by 5 to 25 percent for residences within 1 mile of new station sites and decrease by up to 20 percent within about 400 feet of the alignments or layover facilities. It is not possible to predict with any precision the property tax revenue changes that may result for each community.

The Corridor Plan indicates that, under Scenario 1, the South Coast Rail project would indirectly generate between $16 million and $18 million in net new state taxes and $8.5 million to $9.5 million in net new local business property taxes each year by 2030 as compared to the No Build Alternative.[39] The estimated overall growth (forecast regional growth plus growth attracted to station sites and new induced growth) near rail stations would result in $62 million to $77 million in local property taxes.[40]

Implementing the Smart Growth initiatives in Scenario 2 is expected to change the location of economic impacts such as property tax revenue sources in each affected community, but is not expected to

change the overall (regional) impacts as compared to Scenario 1. See Chapter 5 for further information on indirect effects, and Scenario 1 and 2.

4.4 ENVIRONMENTAL JUSTICE

4.4.1 Introduction

This chapter identifies environmental justice populations within and adjacent to the South Coast Rail alternatives corridors and evaluates potential impacts to these populations that may result from the proposed South Coast Rail alternatives.

4.4.1.1 Resource Definition

Environmental justice is an important element of policy-making in transportation planning. Environmental justice policies focus on improving the natural environment in traditionally underserved communities, addressing disproportionate adverse environmental impacts that exist in those communities, and providing enhanced opportunities for participation in the decision-making process for those actions that may result in beneficial and/or adverse effects. One of the South Coast Rail project's goals is to improve transit services which would also likely provide benefits to environmental justice populations in terms of improved mobility and regional access.

Massachusetts's environmental justice policy[1] characterizes environmental justice populations as neighborhoods, comprised of block groups defined by the U.S. Census Bureau, which meet one or more of the following criteria:

- Median annual household incomes are at or below 65 percent of the statewide median ($30,515 in 2000);
- Minority residents comprise 25 percent or more of the population;
- Foreign-born residents comprise 25 percent or more of the population; or
- Residents with limited English language proficiency represent 25 percent or more of the population.

4.4.1.2 Regulatory Context

The *Environmental Justice Policy*[2] of the Massachusetts EEA[3] is an effort to protect the environment and public health in the Commonwealth. Environmental justice is based on the principle that all people have the right to be protected from environmental pollution and to live in and enjoy a clean and healthful environment. EEA's *Environmental Justice Policy* makes environmental justice an integral consideration in the implementation of all state environmental programs including, but not limited to, granting financial resources, implementing and enforcing laws, regulations, and policies, and providing access to both active and passive open space. The policy focuses attention on minority and low-income neighborhoods in Massachusetts where residents have traditionally been unaware of or unable to participate in environmental decision-making or to gain access to state environmental resources.

[1] Executive Office of Energy and Environmental Affairs (EEA). 2002. Environmental Justice Policy of the Massachusetts Office of Energy and Environmental Affairs. Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs.

[2] EEA. 2002. Environmental Justice Policy of the Massachusetts Office of Energy and Environmental Affairs, Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs.

[3] Formerly known as the Massachusetts Executive Office of Environmental Affairs.

This chapter addresses the requirements of the statutes, regulations, and guidance documents listed below.

- Executive Order (EO) 12898[4] states "each Federal agency shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies and activities on minority and low-income populations."

- The Army Corps of Engineers, in complying with EO 12898, utilizes the guidance provided by the USEPA. USEPA defines environmental justice as "The fair treatment and meaningful involvement of all people, regardless of race, color, national origin or income with respect to the development, implementation, and enforcement of environmental laws, regulations and policies. Fair treatment means that no group of people, including racial, ethnic, or socio-economic groups should bear a disproportionate share of the negative environmental consequences resulting from industrial, municipal and commercial operations or the execution of federal, state, local and tribal programs and policies."[5] USEPA has responsibility for the consideration of environmental justice in Clean Air Act reviews.

- The Federal Transit Administration (FTA), Federal Railroad Administration (FRA) and Federal Highway Administration (FHWA) are U.S. Department of Transportation (DOT) agencies which are Cooperating Agencies for this Federal Action. U.S. DOT Order 5610.2,[6] Environmental Justice in Minority and Low-Income Populations, requires all DOT agencies to determine whether activities will have an adverse impact on minority and low-income populations. DOT agencies must determine if adverse effects are predominantly borne by a low-income or minority population and if adverse effects are appreciably more severe than the adverse effect that would be suffered by the non-minority or non-low-income population.

The Secretary of the Executive Office of the EEA issued a Certificate on the ENF on April 3, 2009. Included in the Certificate are a number of requirements defining the scope of the DEIR, including environmental justice:

- The DEIR should define and include maps identifying the location of environmental justice populations in the project area.

- The DEIR should describe specifically how the project will provide tangible benefits to environmental justice communities identified in the ENF.

- The DEIR should identify any potential for disproportionate impacts on environmental justice communities that may result from the proposed project, including with regard to traditional cultural properties, and any specific proposed mitigation. This includes

[6] US Department of Transportation. 1997. Department of Transportation (DOT) Order to Address Environmental Justice in Minority Populations and Low-Income Populations. Federal Register, Vol. 62, No. 72, pages 18377-18381. Washington, DC. The DOT Order was revised in May 2012- http://www.fhwa.dot.gov/environment/environmental_justice/ej_at_dot/order_56102a/index.cfm.

identifying potential adverse effects on any traditional cultural properties of significance to Native American Tribes, and mitigation. The DEIR should include a list of specific mitigation commitments to address noise and vibration impacts to environmental justice neighborhoods. Mitigation should include specific commitments on how [increased property values in environmental justice communities] will be addressed, and specify how [financial impacts to environmental justice communities in Fall River as a result of property acquisition] will be mitigated as part of the project.

- The DEIR should include an update on MassDOT's outreach efforts to environmental justice populations.
- The DEIR should evaluate safety impacts in the context of the *Environmental Justice Policy* including strategies to enhance public participation in the environmental review process. [7]

The Secretary's Certificate on the DEIR/DEIS required further analysis or discussion of certain impacts to environmental justice populations in the FEIR. The Certificate stated that the FEIR should:

- Include a list of specific mitigation commitments to address noise and vibration impacts to environmental justice neighborhoods;
- Include an update on the investigation of potential adverse effects on any traditional cultural properties of significance to Native American Tribes. The FEIR should clarify if there will be a disproportionate adverse impact to an environmental justice community with regard to traditional cultural properties, and if so, what mitigation will be implemented;[8]
- Specify how financial impacts to environmental justice communities in Fall River as a result of property acquisition] will be mitigated as part of the project;
- Include further discussion and specific commitments on how [increased property values in environmental justice communities] will be addressed (for example, clear commitments to affordable housing as part of the project's station TOD plans, or other measures);
- Include an update on MassDOT's outreach efforts to environmental justice populations; and
- Evaluate safety impacts in the context of EEA's Environmental Justice policy.

4.4.1.3 Methodology

This section summarizes the methodology used to evaluate the potential direct (occurring at the same time and place as the action) and indirect effects (removed in time and space from the action, but still reasonably foreseeable) of the South Coast Rail project on environmental justice populations.

Evaluation of Direct Effects

Potential direct effects to environmental justice populations were evaluated for residence or job losses due to property acquisition, neighborhood fragmentation, increases in noise levels and impacts to other

[7] Certificate of the Secretary of Energy and Environmental Affairs on the Environmental Notification Form. South Coast Rail Project. April 3, 2009.

[8] Refer to Chapter 4.8 Cultural Resources for all information pertaining to traditional cultural properties.

resources. If any impacts to these resources in environmental justice neighborhoods were found to be substantive, then a comparison of impacts to non-environmental justice neighborhoods was made to determine if the significant adverse impact would be predominantly borne by environmental justice populations or whether it is appreciably more severe or greater in magnitude than the adverse impact that will be suffered by the non-environmental justice population in the same community. Environmental justice neighborhoods were defined at the Census block group level based on median household income, presence of those who identify themselves as being of a minority, foreign-born residents, and those with limited English proficiency.

Property acquisition requirements in environmental justice neighborhoods were identified by reviewing areas where construction would be required for each of the alternatives with respect to those neighborhoods to determine where the rail corridors, stations, or layover facilities would pass through or be located within them. For the purposes of this evaluation, "construction" is defined as upgrading existing rail lines, reconstructing removed rail lines along out-of-service railroad alignments, constructing new railroads, replacing existing railroad bridges and culverts, constructing new permanent or temporary railroad bridges, reconfiguring at-grade road/railroad crossings, and constructing new grade-separated road/railroad crossings. Environmental justice neighborhoods were outlined by Census block group according to the criteria cited above, and plotted on aerial photographs with the preliminary plans of each alternative for the evaluation.

"Property Acquisition" is defined as taking a greater than 500-square-foot portion, or a sliver greater than 10 feet wide, of any parcel outside of the existing right-of-way to accommodate permanent impacts, and is based upon preliminary engineering plans. Temporary construction impacts outside of the existing right-of-way would not require property acquisition and are not considered in this evaluation. Slivers less than 10 feet wide or temporary construction easements were not considered in the evaluation of property acquisition because given the scale and accuracy of the preliminary engineering plans, these are likely to be eliminated in final design. Maps and aerial photographs were examined in reference to preliminary engineering plans to identify encroachments into environmental justice neighborhoods. Final engineering plans may show an increase or decrease of the actual area of acquisition required. Adverse impacts to environmental justice populations were determined if the property acquisition would result in loss of residences or jobs. Such impacts would be further characterized as substantive if they represent a large portion of total residencies or jobs in a community and are located in a neighborhood with a high concentration of low-income and/or minority residents.

Neighborhood fragmentation was evaluated by examining aerial photographs and observing environmental justice neighborhoods to qualitatively determine if neighborhood continuity across the alignments would be disrupted by any of the alternatives.

Selected other environmental impacts to environmental justice populations were also evaluated. Because disproportionate impacts to environmental justice communities are predicated on the potential for significant impacts in other environmental categories, only the environmental impact categories with significant impacts under the Build Alternatives were studied in detail in this analysis. The specific topics included in the environmental justice assessment are: socioeconomics, noise, and vibration. Issues related to traditional cultural properties are addressed in Chapter 4.8, *Cultural Resources*. Direct impacts to environmental justice populations from changes in these other resources were evaluated in relationship to the environmental justice neighborhoods.

For each of these resource areas, substantive adverse impacts in environmental justice neighborhoods were compared with impacts in non-environmental justice neighborhoods to determine if environmental justice populations would be disproportionately impacted. This comparison of adverse impacts was conducted on a regional basis (the South Coast Rail study area) to coincide with the evaluation of regional benefits that would be realized by environmental justice populations as indirect effects, described below.

The following topics would not have the potential to result in significant adverse impacts on environmental justice populations and were not evaluated in detail as part of this environmental justice assessment:

- Chapter 4.9, *Air Quality*, includes a review of ambient air quality and modeled emissions from the trains to identify where adverse impacts to air quality would occur, including within environmental justice neighborhoods. The study concluded that the electric train alternatives would not adversely impact local air quality, and the diesel train alternatives' impact would be very small (less than a 1.5-percent increase in pollutant levels) and would not result in air pollutant concentrations in excess of the National Ambient Air Quality Standards (NAAQS). Based on this conclusion, there would be no air quality impacts to environmental justice populations.

- Chapter 4.10, *Protected Open Space and Areas of Critical Environmental Concern*, identifies where acquisition of protected open space or publicly owned parcels within ACECs would adversely impact these properties. While the alternatives do involve the acquisition of protected open space, these acquisitions do not occur in environmental justice areas and thus do not have the potential to disproportionally impact environmental justice populations.

Temporary impacts were not evaluated in detail because they would be mitigated through construction best management practices and any impacts after mitigation would not have a lasting effect on adjacent communities.

Evaluation of Indirect Effects

Potential indirect effects to environmental justice populations were also evaluated based on the review of station alternatives with respect to environmental justice neighborhoods. This analysis also included a review of indirect impacts to environmental justice populations in nearby communities likely served by the stations. Potential benefits to environmental justice communities are an indirect effect of the South Coast Rail project. A study[9] conducted by the Central Transportation Planning Staff (CTPS) of the Boston Metropolitan Planning Organization examined how the South Coast Rail alternatives would affect travel accessibility and mobility for environmental justice populations in Taunton, Fall River, and New Bedford. Results of that study are incorporated in this chapter; the study is provided in Appendix 4.4-A.

Potential indirect socioeconomic impacts due to changes in property values were evaluated qualitatively through reference to the *South Coast Rail Economic Development and Land Use Corridor Plan* and the applicable literature.

4.4.2 Existing Conditions

This section discusses the presence of minority, foreign-born, low-income and limited English language proficiency populations within the study area for the South Coast Rail project.

4.4.2.1 Regional Overview of Environmental Justice Populations

Table 4.4-1 lists the communities that would be served or that could be impacted by the alternatives under consideration.[10] The South Coast Rail alternative railroad alignments pass through or near these 27 communities, and new station sites are within or near each. These communities constitute the environmental justice study area.

Table 4.4-1 Environmental Justice Study Area Communities

Fairhaven	North Attleborough	Taunton
Fall River	Norton	Westport

Low-income and minority populations in the South Coast Rail environmental justice study area are generally located in densely populated neighborhoods. These neighborhoods are frequently near contaminated sites, abandoned sites, and large sources of air pollution.

Portions of the following eight municipalities within the South Coast Rail environmental justice study area include environmental justice neighborhoods that may be directly affected or benefit from the service provided by the Stoughton or Whittenton Alternatives:

- Canton
- Stoughton
- Taunton
- Fall River
- New Bedford
- Dartmouth
- Fairhaven
- Swanson

Table 4.4-2 provides an overview of state-listed environmental justice communities as a percent of total municipal acreage. Such a designation comes from the regulatory framework for conducting environmental justice analysis in Massachusetts. Tables 4.4-3 and 4.4-4 identify the presence of

[10] The study area includes communities exclusively associated with alternatives included in the DEIS/DEIR but not advanced to the FEIS/FEIR, (Attleboro and Rapid Bus) as described in Chapter 3 – Alternatives. These communities would not be impacted by the Stoughton and Whittenton alternatives analyzed in this FEIS/FEIR.

environmental justice populations (minority, low income, foreign-born, and limited English proficiency) and minority populations, respectively, in these ten communities.

Table 4.4-2 State-Listed Environmental Justice Areas[1] in South Coast Communities

Municipality	Total Municipal Acreage	Acreage within Designated Environmental Justice area	Percent Designated as Environmental Justice Area: Designated Environmental Justice area	Defined By Specific Criteria: Foreign-Born	Low Income	Minority	English Proficiency
Canton	12,489	190	1.5	0.0	0.0	1.5	0.0
Dartmouth	39,653	1,044	2.6	1.6	1.0	0.0	0.0
Fairhaven	7,942	223	2.8	0.0	2.8	0.0	0.0
Fall River	24,668	3,705	15.0	4.5	13.5	1.9	0.2

Source: U.S. Census data (2000), MassGIS.
1 Environmental justice areas can be designated based on multiple independent criteria. The table presents the cumulative population in environmental justice areas for all criteria.

As a whole, less than three percent of the land area of the 27 South Coast communities in the study area has an environmental justice neighborhood designation. These environmental justice neighborhoods contain approximately 21 percent of the population of the 27 communities. Approximately 84 percent of the total environmental justice population is located in Fall River or New Bedford, and approximately 45 percent of the environmental justice neighborhood land area is within these two communities.

The eight municipalities are primarily comprised of those who identify themselves as White, with varying shares of those who identify themselves as Black or African American, Asian, American Indian or

Alaska Native, Native Hawaiian or Other Pacific Islander, multiracial, and Hispanic or Latino residents, based on definitions from the U.S. Office of Management and Budget[11] and data from the U.S. Census.[12] Overall, minority populations represent less than 10 percent of the total population in each of the seven municipalities, with the exception of New Bedford where approximately 21 percent of the population identifies itself as a minority and Stoughton where 11.5 percent of the population identifies itself as the same. Each of the eight communities, with the exception of New Bedford, has a smaller percentage of minority populations than the statewide average of 15.5 percent. Those who identify themselves as Hispanic is the most common minority population in Fall River, New Bedford, and Taunton. The minority population in Fairhaven and Swansea is primarily multiracial and Dartmouth is identified as "Other."

Table 4.4-4 Racial and Ethnic Composition of South Coast Communities

		Percent of Population by Race							
Municipality	Total Population	White	Black	American Indian	Asian	Pacific Islander	Other	Multiracial	Hispanic[1]
Canton	20,775	92.5	2.9	0.1	3.0	0.0	0.5	0.9	1.4
Dartmouth	30,666	90.6	1.1	0.2	1.7	0.0	5.0	1.4	1.5
Fairhaven	15,821	96.2	0.6	0.0	0.3	0.0	0.8	2.0	0.5
Fall River	87,395	91.1	2.8	0.2	2.1	0.0	1.3	2.6	3.4
Mansfield	22,414	93.5	2.5	0.2	2.0	0.1	0.2	2.5	0.5
New Bedford	93,065	79.2	4.4	0.5	0.7	0.1	9.1	6.0	10.0

Source: U.S. Census data (2000), MassGIS.
1 Hispanic populations are generally included as subsets within the other racial categories but are listed separately as well for clarity. Therefore, the percentages for each city will add up to more than 100 percent.

People who are physically, economically, or socially disadvantaged often have less access to an automobile and may face barriers to mobility. The correlation between automobile access and environmental justice populations was evaluated for the South Coast Rail environmental justice study area. Registered motor vehicle data were reviewed for each of the South Coast communities in the environmental justice study area (Table 4.4-5). Decennial Census data from 2000 reveals a negative correlation between environmental justice populations in the study area and the percentage of households reporting registered motor vehicles. Fall River and New Bedford, which have the greatest percentage of their total population being classified as protected under environmental justice regulations, reported the highest percentage of households without motor vehicles, at approximately 21 percent and 22 percent, respectively.

All other study area communities were below the statewide average of 12.7 percent of zero-car households. Fairhaven, Berkley, Rochester, Raynham, Dighton, and Freetown all reported motor vehicle ownership at greater than 97 percent of all households.

Note Communities above the statewide average are identified in bold.

4.4.2.2 Environmental Justice Populations within a 0.5 Mile of Proposed Alternatives

Environmental justice populations within 0.5 mile of the alternative alignments are summarized in Table 4.4-6 and described in subsequent sections. Accompanying figures show communities meeting environmental justice criteria based on minority, foreign-born, low income, and/or limited English proficiency populations along each alternative alignment and near each station.

Southern Triangle

In 2000, the population within 0.5 mile of the Fall River Secondary Rail Segment was 52,021 and the population within 0.5 mile of the New Bedford Main Line Rail Segment was 71,001.[13] As presented on Figures 4.4-1a-e and 4.4-2a-c, environmental justice populations were identified primarily along the southern urban portion of both the New Bedford Main Line and Fall River Secondary in New Bedford and Fall River, respectively. Residents living in these neighborhoods most commonly meet low income and/or minority criteria. Neighborhoods with foreign-born residents were also identified along the New Bedford Main Line between the Acushnet River and the railroad, between Nash Street and Wamsutta Street. Foreign-born and low income residents were also identified south of the end of the Fall River Secondary.

Table 4.4-6 Summaries of State-Listed Environmental Justice Populations within 0.5 Mile of the Alternative Alignments

Alternative Alignment	Percentage of Total Population Living within a Designated Environmental Justice Area–Defined by Any Criterion[1]	Primary Criteria for Designation
Fall River Secondary Rail Segment	36.0	Low Income
New Bedford Main Line Rail Segment	50.4	Minority
Stoughton Electric Alternative and Stoughton Diesel Alternative	9.1	Low Income
Whittenton Electric Alternative and Whittenton Diesel Alternative	9.1	Low Income

Source: U.S. Census data (2000), MassGIS.
The table presents the cumulative environmental justice areas for all criteria.

Stoughton Alternatives

In 2000, the population within 0.5 mile of the Stoughton Alternatives was 88,744. This includes residents along the Stoughton Line from Canton Junction to Weir Junction, and along New Bedford Main Line from Weir Junction to Cotley Junction. Environmental justice populations were identified within 0.5 mile the Stoughton Alternatives under the minority (0.8 percent), foreign-born (0.6 percent), and low income (1.5 percent) criteria. As shown on Figures 4.4-3a-e, environmental justice populations identified along the Stoughton Alternatives are concentrated along the northern portion of the route in Canton (minorities) and Stoughton (foreign-born), and along the southern portion of the alignment in Taunton (low income).

Whittenton Alternatives

In 2000, the population within 0.5 mile of the Whittenton Alternatives was 91,951. This includes the population along the Stoughton Line from Canton Junction to Weir Junction, and the New Bedford Main Line from Weir Junction to Cotley Junction. There are no environmental justice populations within 0.5 mile the Whittenton Branch between Raynham Junction and Whittenton Junction. Environmental justice populations were identified within 0.5 mile of the Whittenton Alternatives under the minority (0.9 percent), foreign-born (0.6 percent), and low income (1.6 percent) criteria. As shown on Figure 4.4-4, environmental justice populations identified along the Whittenton Alternatives are concentrated along the Attleboro Secondary in Taunton. The southernmost environmental justice population (at the

[13] Populations are based on MassGIS data, which presents information in block groups. Included in the calculation of population are all block groups that intersect the 0.5 mile buffer of each alternative alignment and station site.

intersection of the Stoughton Line and Attleboro Secondary, near Weir Junction) meets the low income criteria, while the northern environmental justice area is based on the concentration of minority and low income residents.

Stations

Because the greatest impacts—both adverse and beneficial—to designated environmental justice communities would likely be experienced in those areas within close proximity to proposed stations, a study area of 0.5 mile from proposed stations was identified. This section describes state-listed environmental justice populations within 0.5 mile from proposed station locations (Table 4.4-7).

Table 4.4-7 State-Listed Environmental Justice Populations within 0.5 Mile of the Proposed Station Sites

	Percent of Total Population Living within a Designated Environmental Justice Area[1]				
	Defined by Any	Defined By Specific Criteria			
Station Site	Criterion2	Foreign-Born	Low Income	Minority	English Proficiency3

Source: U.S. Census data (2000), MassGIS.

1 Environmental justice areas can be designated based on multiple independent criteria. The table presents the cumulative environmental justice areas for all criteria as well as the total area designated by the specific criteria indicated.

2 MassGIS calculates environmental justice populations assuming the entire sample population within an environmental justice-designated block group is an environmental justice population. If a block group meets one or more environmental justice criteria, then all population within that block group is considered as part of the environmental justice population. Additionally, environmental justice populations may meet one or more criteria for designation; therefore, the total percentage of environmental justice populations defined by any criterion is not a sum of the percentage of each individual criterion.

3 English language proficiency data are calculated based on households, not population, and total household information is not provided for block groups. However, the overall English language proficiency was calculated for the population within 0.5 mile of the Battleship Cove Station assuming the same percentage of households are within each block group, as population (for example, if 10 percent population is within one block group, then 10 percent of the households are within the block group also). When more than one block group reported households meeting the English language proficiency environmental justice criteria, the average percentage was calculated for these block groups.

Station Sites Common to All Rail Alternatives

Both the Stoughton and Whittenton Alternatives would have eleven new commuter rail stations. Ten stations are common to all rail alternatives. The Taunton (Dean Street) Station would be constructed under the Stoughton Alternatives while the Dana Street Station, also in Taunton, would be constructed under the Whittenton Alternatives.

A brief discussion of each station is provided below, including an evaluation of state-listed environmental justice populations within 0.5 mile of each station. Those stations common to both rail alternatives are listed first and the two unique stations are provided at the end of this section.

Stoughton Station—The relocated Stoughton Station would be shifted from its present location between Porter and Wyman streets to a new location south of the Wyman Street at-grade crossing (see Chapter 3). The proposed station site is privately owned and is currently occupied by commercial and industrial uses, including warehouses/office space used by the Alpha Chemical Company and property of the Murphy Coal Company (fuel storage and materials handling yard, parking lot, and vehicle repair garage).

The Stoughton Station site is surrounded by developed land in the center of Stoughton. Land uses within 0.5 mile of the relocated Stoughton Station include a mix of industrial, commercial, and residential, along with community facilities such as the Stoughton Public Library.

In 2000, the population of Stoughton was 27,149, while the population within 0.5 mile of Stoughton Station was 4,121. Environmental justice neighborhoods were identified within 0.5 mile of the site under the foreign-born (26.7 percent) criterion, as summarized in Table 4.4-7. Environmental justice communities in the vicinity of the relocated Stoughton Station are shown in Figure 4.4-3a. Environmental justice-classified foreign-born residents were identified on the northern, eastern and western sides of the proposed Stoughton station.

King's Highway Station Site—The King's Highway Station, in northern New Bedford along King's Highway east of Route 140, would occupy part of an approximately 55-acre site that is now a shopping plaza. The site would serve walk-in, bike-in, and drive-in customers.

In 2000, the population of New Bedford was 93,768, while the population within 0.5 mile of the King's Highway Station site was 5,866. Environmental justice neighborhoods were identified within 0.5 mile of the site under the low-income (2.6 percent) criteria, as summarized in Table 4.4-7 and shown on Figure 4.4-5. Environmental justice-classified low-income residents were identified along the eastern side of the New Bedford Main Line, approximately 0.5 mile south-southeast of the King's Highway Station site.

Whale's Tooth Station Site—The Whale's Tooth Station, at the Whale's Tooth parking lot, would be sited on an approximately 14-acre parcel on the New Bedford waterfront and was identified as the preferred site in the 2002 Final EIR on South Coast Rail. The City of New Bedford has constructed a parking lot on the site in anticipation of the South Coast Rail project. The station would include intermodal connections, potentially including ferry services. The site would serve walk-in, bike-in and drive-in customers.

In 2000, the population of New Bedford was 93,768, while the population within 0.5 mile of the Whale's Tooth Station site was 10,067. Environmental justice neighborhoods were identified within 0.5 mile of the site under the minority (37.6 percent), foreign-born (12.4 percent) and low-income (24.3 percent) criteria (Table 4.4-7 and Figure 4.4-6). Nearly all residents living within 0.5 mile of the proposed Whale's Tooth Station site are classified as environmental justice populations under the minority and low-income designation. A neighborhood approximately 0.4 mile north of the Whale's Tooth Station site is classified as environmental justice based on foreign-born residents, as well as minority and low-income resident concentrations.

Freetown Station Site—The Freetown Station on South Main Street would be located on an approximately 18-acre site is currently industrial and occupied by a self-storage business, and is near the Fall River Executive Park and the River Front Park. The vicinity of the proposed site is mainly forested, agricultural, and undeveloped, with some residential and industrial uses. The site would serve drive-in customers and customers shuttled between the station and the industrial parks.

In 2000, the population of Freetown was 8,472, while the population within 0.5 mile of the Freetown Station site was 1,002. Environmental justice neighborhoods were not identified within 0.5 mile of the site. Although minority, low-income, foreign-born, and limited English proficiency residents were reported within 0.5 mile of the Freetown Station site, these populations were not reported in concentrations high enough to meet Massachusetts' environmental justice criteria and therefore, are not considered environmental justice neighborhoods.

Fall River Depot Station Site—The Fall River Depot Station, 1 mile north of downtown Fall River at Route 79 and Davol Street, is currently occupied primarily by private commercial and industrial property, although a portion is owned by the City of Fall River.

In 2000, the population of Fall River was 91,938, while the population within 0.5 mile of the Fall River Depot Station site was 9,336. Environmental justice neighborhoods were identified within 0.5 mile of the site under the minority (5.1 percent) and low-income (50.1 percent) criteria (Table 4.4-7 and Figure 4.4-7). Environmental justice populations identified within 0.5 mile of the Fall River Depot Station site are due primarily to the concentrations of low-income residents. Neighborhoods meeting the minority and low-income environmental justice criteria were also identified along the Fall River Secondary, south of the Fall River Depot Station site, between Taylor Street and North Central Street.

Battleship Cove Station Site—The Battleship Cove Station, an approximately 2.2-acre site on the Fall River waterfront behind the Ponte Delgada Plaza, is anticipated to be a platform-only station and would be designed to serve walk-in customers, and pick–up/drop-off customers. The station would serve the downtown area and the Battleship Cove tourist area. The City of Fall River constructed a pick-up/drop-off loop road for the future commuter rail station as part of the Ponte Delgada Plaza.

In 2000, the population of Fall River was 91,938, while the population within 0.5 mile of the Battleship Cove Station site was 12,353. Environmental justice neighborhoods were identified within 0.5 mile of the site under the minority (5.5 percent), low-income (14.3 percent), foreign-born (22.3 percent), and English language proficiency (7.2 percent) criteria (Table 4.4-7 and Figure 4.4-8). Nearly the entire population surrounding the Battleship Cove Station site is classified within one of six environmental justice areas. Residents within 0.5 mile of the Battleship Cove Station site primarily meet the low-income environmental justice criterion, though foreign-born and minority populations are also present to the south.

North Easton Station Site—The North Easton Station would be located at the rear of the Roche Brothers Shopping Plaza. This retail plaza, anchored by a Roche Brothers Supermarket, occupies an approximately 10-acre site. New medical buildings have been constructed nearby and two additional buildings are planned. The station would likely share parking facilities with the medical buildings and would primarily serve drive-in customers, although the station may attract some walk-in customers from the shopping plaza and from nearby residential developments in Stoughton and Easton.

In 2000, the population in Stoughton was 27,149, in Easton 22,299, and the population within 0.5 mile of the North Easton Station site was 6,375. Environmental justice neighborhoods were not identified

within 0.5 mile of the site. Although minority, low-income, foreign-born, and residents with limited English proficiency were reported within 0.5 mile of the North Easton Station site, these populations were not reported in concentrations high enough to meet Massachusetts' environmental justice criteria and, therefore, are not considered environmental justice neighborhoods.

Easton Village Station Site—The Easton Village Station would be sited south of the historic H.H. Richardson train station. The site is limited to the railroad right-of-way and is within walking distance of downtown Easton. The site would be a village-style station serving walk-in and bike-in customers.

In 2000, the population in Easton was 22,299, while the population within 0.5 mile of the Easton Village Station site was 6,831. Environmental justice neighborhoods were not identified within 0.5 mile of the site. Although minority, low income, foreign-born, and residents with limited English proficiency were reported within 0.5 mile of the Easton Village Station site, these populations were not reported in concentrations high enough to meet Massachusetts' environmental justice criteria and therefore, are not considered environmental justice neighborhoods.

Raynham Park Station Site—The Raynham Park Station, at the former Raynham-Taunton Greyhound Park in Raynham, is now occupied by a simulcast/off-track betting facility and has large surface parking lots along Route 138 near the Raynham/Easton town line. The station would be on a portion of this approximately 80-acre site. The site would be designed to serve mostly drive-in customers with additional walk-in customers being drawn from future redevelopment on or near the site.

In 2000, the population of Raynham was 11,739, while the population within 0.5 mile of the Raynham Park Station site was 2,438. Environmental justice neighborhoods were not identified within 0.5 mile of the Raynham Park Station site. Although minority, low income, foreign-born, and limited English language proficiency residents were reported within 0.5 mile of the Raynham Park Station site, these populations were not reported in concentrations high enough to meet Massachusetts' environmental justice criteria and therefore, are not considered environmental justice neighborhoods.

Taunton Depot Station Site—The Taunton Depot Station, at the rear of the Target Plaza, would be located on a site approximately 14 acres in size and accessible via Route 140. The shopping plaza is a newer big-box retail site that contains Target, Home Depot, and other stores. The station would serve customers that drive to the station, as well as potential future walk-in or bike-in customers if redevelopment were to occur.

In 2000, the population of Taunton was 55,976, the population of Berkley was 5,749, and the population within 0.5 mile of the Taunton Depot station site was 6,320. Environmental justice neighborhoods were not identified within 0.5 mile of the site. Although minority, low income, foreign-born, and limited English language proficiency residents were reported within 0.5 mile of the Taunton Depot Station site, these populations were not reported in concentrations high enough to meet Massachusetts' environmental justice criteria and therefore, are not considered environmental justice neighborhoods.

Station Sites that Differ Between the Rail Alternatives

Taunton (Dean Street) Station Site – Stoughton Alternatives—The Taunton Station is at the Dean Street site (Figure 4.4-19). The site is approximately 8 acres and is near Route 44 just north of the historic train station. Downtown Taunton is approximately 0.75 to 1 mile from the site. The site is bounded by Arlington Street, Belmont Street and the existing railroad and is primarily vacant. Currently, parcels comprising the site are owned by the City and by private entities. The City-owned parcel was a former

rubber plant that burned. The City of Taunton has invested in remediating this Brownfield site in anticipation of a future train station. The site is within walking distance of downtown and would be utilized for future TOD. The site would be a multi-modal transportation center serving walk-in, bike-in, and drive-in customers.

Adjacent parcels are forest to the north and east, residential to the west, and commercial to the south. Industrial, institutional (nursing home), and recreational/municipal (ball fields) properties interspersed with forest are east of the railroad right-of-way, and accessed from Longmeadow Road or Dean Street. Moderate-density residential is the predominant land use within 0.5 mile of the Taunton Station site, particularly north and west. A few commercial, industrial, and religious use, and undeveloped parcels are scattered throughout the vicinity.

In 2000, the population of Taunton was 55,976, while the population within 0.5 mile of the Taunton Station site was 8,252. Environmental justice neighborhoods were identified within 0.5 mile of the site under the low-income (5.8 percent) criterion, as summarized in Table 4.4-7 and shown on Figure 4.4-9. Environmental justice areas were identified approximately 0.4 mile west of the Taunton Station site. Residents in this environmental justice area meet the low-income criterion for designation.

Dana Street Station Site – Whittenton Alternatives—The Dana Street Station would be located just south of the Danforth Street grade crossing, within walking distance of downtown Taunton. The site is currently a vacant lot. Surrounding land uses include industrial, residential, and agricultural. The station would serve walk-in, bike-in, and drive-in customers.

In 2000, the population of Taunton was 55,976, while the population within 0.5 mile was 2,882. Environmental justice neighborhoods were identified within 0.5 mile of the proposed Dana Street station site which meet the low income (17.9 percent) and minority (28.6 percent) criteria, summarized in Table 4.4-7 and shown on Figure 4.4-10. The area west of the Dana Street station site is classified as an environmental justice neighborhood based on the percentage of low income and minority residents, but populations immediately adjacent to the station site were not reported in concentrations high enough to meet Massachusetts' environmental justice criteria.

Layover Facilities

Both the Stoughton and Whittenton Alternatives (diesel and electric alternatives) would require two overnight layover facilities—one on the Fall River Branch and one on the New Bedford Main Line.

Weaver's Cove East Facility Site

The proposed Weaver's Cove East site layover facility would be located on the east side of the right-of-way, opposite the formerly proposed Weaver's Cove LNG Site in Fall River (Figure 4.4-11). It would be located approximately 1.5 miles north of Fall River Depot Station and 2.6 miles north of Battleship Cove Station.

Currently vacant land, a portion of the Weaver's Cove East site was previously developed. Approximately one-half of the site is cleared of vegetation or includes remnant building foundations; the remainder of the site is vegetated. Surrounding land to the north, east, and south is residential; industrial land use is present to the southwest. Undeveloped land is immediately west of the site, adjoining the Taunton River. The industrial site to the southwest is a former Shell Oil facility, and

consists of completely cleared land with several large aboveground storage tanks and a short shipping dock.

Although there are no environmental justice communities within the layover site, an environmental justice neighborhood is located south of the proposed layover facility, to the east of the Fall River Secondary Rail Segment. Residents living within this neighborhood meet low income criteria for designation.

Wamsutta Facility Site

The proposed Wamsutta site layover facility would be located on the east side of the right-of-way, opposite the proposed Whale's Tooth Station and adjacent to an existing CSX freight yard (Figure 4.4-12). The site would be located 0.3 mile north of Whale's Tooth Station. The area is primarily characterized by industrial land uses and no commercial or residential properties or open space areas are located within close proximity to this site.

The Wamsutta site layover facility is located within an environmental justice neighborhood that meets low income and minority criteria for designation. Adjacent to the north of the proposed layover facility is an environmental justice neighborhood that also meets foreign-born criteria for designation.

Summary

The data indicate the South Coast Rail environmental justice study area has a substantial environmental justice population based on MassGIS criteria for determining such populations. The area around the Southern Triangle alignments contains the largest percent of the population (36 percent around the Fall River Secondary Rail Segment and 50.4 percent around the New Bedford Main Line Rail Segment) living within environmental justice-designated neighborhoods (as defined by block groups). Environmental justice populations living within 0.5 mile of the alternative alignments are primarily classified based on the low income criterion with the exception of the New Bedford Main Line Rail Segment where minority populations comprise the majority of the environmental justice designations.

MassGIS-designated environmental justice neighborhoods were identified within 0.5 mile of 7 of the 12 proposed station sites (see Table 4.4-8). The area within 0.5 mile of the Battleship Cove Station site in Fall River contains the largest percentage of population living within environmental justice-designated neighborhoods, at 88.7 percent. Low income was identified as the primary criteria for environmental justice designation around these station sites.

In general, the highest concentration of environmental justice populations is present near the southern portion of the Southern Triangle in urban areas of Fall River and New Bedford. The primary criterion for environmental justice designation in these areas is low income, although concentrations of minority and foreign-born residents were also identified in the study area, in particular, around proposed station sites. In many cases, populations met more than one of the environmental justice criteria, such as low income and minority, or foreign-born, minority, and low income. Environmental justice populations identified in New Bedford and Fall River were more widespread and diverse (met more criteria for environmental justice) than the populations in other towns in the South Coast region. Environmental justice populations in the other towns in the South Coast area, such as Canton, Stoughton, or Taunton, had moderate to high concentrations of environmental justice populations meeting one or two criteria for designation.

Table 4.4-8 Summary of State-Listed Environmental Justice Populations within 0.5 Mile of the Proposed Station Sites

Station Sites	Percentage of Total Population Living within a Designated Environmental Justice Area–Defined by Any Criterion[1,2]	Population Living within a Designated Environmental Justice Area–Defined by Any Criterion[1,2]	Primary Criteria for Designation
Stoughton	26.7	520	Foreign Born
King's Highway	20.9	1,213	Low Income
Whale's Tooth	85.6	8,937	Minority
Freetown	0.0	0	N/A
Fall River Depot	50.2	4,652	Low Income
Battleship Cove	88.7	10,965	Foreign-Born
North Easton	0.0	0	N/A
Easton Village	0.0	0	N/A
Raynham Park	0.0	0	N/A
Taunton	21.1	1,857	Low Income
Dana Street	27.7	411	Minority
Taunton Depot	0.0	0	N/A

Source: U.S. Census data (2000), MassGIS.

1 Environmental justice areas can be designated based on multiple independent criteria. The table presents the cumulative environmental justice areas for all criteria.

2 MassGIS calculates environmental justice populations assuming the entire sample population within an environmental justice - designated block group is an environmental justice population. If a block group meets one or more environmental justice criteria, then all population within that block group is considered as part of the environmental justice population. Additionally, environmental justice populations may meet one or more criteria for designation; therefore, the total percentage of environmental justice populations defined by any criterion is not a sum of the percentage of each individual criterion.

4.4.3 Impacts and Mitigation

4.4.3.1 Introduction

This section identifies adverse impacts to environmental justice populations as well as any benefits to these populations that may result from the implementation of the South Coast Rail project. Specifically, the evaluation considered property acquisition, change in noise or vibration levels or air quality, and the presence of traditional cultural properties and open space. If adverse impacts were identified, they were further evaluated to determine if state-listed environmental justice communities would experience a disproportionately high and adverse share of these impacts. The evaluation also considered beneficial effects that may be recognized as a result of the South Coast Rail project. Beneficial impacts include improved access to transit services making it easier to reach employment and educational opportunities, general mobility, and improved air quality.

Detailed information regarding potential impacts is provided in pertinent resource chapters in the FEIS/FEIR, including but not limited to Land Use, Socioeconomics, Transportation, Open Space, Visual Resources, Air Quality, Noise, Vibration, and Indirect Effects and Cumulative Impacts.

4.4.3.2 Property Acquisitions

No-Build (Enhanced Bus Alternative)

The improvements to existing bus service under the No-Build Alternative would not require property acquisitions and therefore there would be no property acquisition-related impacts to environmental justice areas.

Southern Triangle (Common to All Rail Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all rail alternatives. These rail lines form a rough triangular shape running south from Myricks Junction to Fall River (Fall River Secondary Rail Segment) and from Weir Junction through Myricks Junction to New Bedford (New Bedford Main Line), and are therefore referred to as the Southern Triangle (Figure 1.4-1).

Fall River Secondary

Along the Fall River Secondary, one privately owned parcel would be acquired within an environmental justice neighborhood for the right-of-way and one parcel for a traction power facility (for the electric alternatives only) (Table 4.4-9 and Figure 4.4-2c).

Table 4.4-9 Fall River Secondary Environmental Justice Property Acquisition

Municipality	Parcel Number	Ownership	Generalized Zoning	General Land Use	Environmental Justice Categories	Area (acres)
Right-of-Way (All Rail Alternatives)						
Fall River	O-23-4	Private	Industrial	Industrial	Income, Minority	0.02
Traction Power Facility (All Electric Alternatives)						
Fall River	O-22-8	Private	Industrial	Commercial	Income, Minority	0.17
TOTAL (Right-of-Way and Traction Power Facility, All Electric Alternatives)						0.19

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

The small portion of the parcel that would be acquired for the right-of-way is along the west side of the Fall River Secondary Rail Segment near the intersection of Davol Street and Cedar Street. The land, which is industrial in nature, is necessary for construction of the upgraded railroad in this segment.

The portion of the parcel that would be acquired for the traction power facility is also along the west side of the Fall River Secondary Rail Segment, adjacent to the proposed Fall River Depot Station. This land is necessary for construction of a parallel substation for the electric alternatives. This parcel is a portion of a vacant industrial property and does not serve residential purposes.

Because of the small size of the acquisitions and the current function of affected parcels, no jobs or residences would be lost. Therefore, no adverse impacts to state-listed environmental justice populations would result.

New Bedford Main Line

One portion of a parcel in an environmental justice neighborhood would be acquired for the New Bedford Main Line right-of-way improvements and one portion of a parcel would be acquired for a traction power facility, as listed in Table 4.4-10 and shown in Figures 4.4-1a and 4.4-1e.

Table 4.4-10 New Bedford Main Line Environmental Justice Property Acquisition

Municipality	Parcel Number	Ownership	Generalized Zoning	General Land Use	Environmental Justice Categories	Area (acres)
Right-of-Way (All Rail Alternatives)						
Taunton	78-188	Public	Industrial	Industrial	Income	0.03
Traction Power Facility (Electric Alternatives)						
New Bedford	84-113	Private	Industrial	Industrial	Income, Minority	0.18
TOTAL (Right-of-Way and Traction Power Facility, Electric Alternatives						**0.21**

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

The parcel in Taunton is along the east side of the right-of-way near Weir Junction. The parcel is identified as publicly owned, but is a small portion of an industrial property. A portion of the parcel is required to allow for construction of the upgraded railroad in this segment. There would be no impact to environmental justice populations from acquiring a small portion of this parcel because there would be no residence or job loss.

The parcel in New Bedford is along the west side of the right-of-way near the intersection of the railroad with Purchase Street. The parcel is a portion of a vacant industrial property. The parcel is required to allow for construction of a parallel substation for the electric alternatives. There would be no impact to environmental justice populations from acquiring a small portion of this parcel because there would be no residence or job loss.

Stoughton Alternatives (Electric and Diesel)

The Stoughton Line is currently used for commuter service from Canton to Stoughton. Rail service from there south to Weir Junction was discontinued in the 1950s and some track removed; however, the right-of-way still exists and the southernmost portion is used for freight service. In Stoughton, portions of four parcels in environmental justice neighborhoods would be acquired for the right-of-way; a portion of one parcel in Taunton would be acquired for a traction power facility, as listed in Table 4.4-11 and shown in Figures 4.4-13 and 4.4-3e.

Table 4.4-11 Stoughton Line: Environmental Justice Property Acquisition

Municipality	Parcel Number	Ownership	Generalized Zoning	General Land Use	Environmental Justice Categories	Area (acres)
Right-of-Way						
Stoughton	053-101	Private	Industrial	Commercial	Foreign-Born	0.04
	053-102	Private	Industrial	Commercial	Foreign-Born	0.06
	054-110	Private	Commercial	Industrial	Foreign-Born	0.24
Subtotal (Electric and Diesel Alternatives)						0.41
Traction Power Facility (Electric Alternative)						
Taunton	78-121	Private	Industrial	Undeveloped	Income	0.36
TOTAL (Right-of-Way and Traction Power Facility, Electric Alternative)						0.77

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

The four parcels in Stoughton are privately owned and located near the existing Stoughton Station. The parcels, which are vacant commercial/industrial property, are required to allow for construction of the upgraded railroad. The parcel in Taunton is privately owned land on the west side of the Stoughton Line right-of-way near Weir Junction; it is zoned for industrial use but the portion that would be acquired under the Stoughton Electric Alternative is undeveloped land. This portion of the parcel would be used for a parallel substation for the Stoughton Electric Alternative. No jobs or residences would be lost from acquiring these parcels.

Whittenton Alternatives (Electric and Diesel)

The property impacts in Stoughton described above for the Stoughton Alternatives would also occur under the Whittenton Alternatives.

There are no environmental justice areas along the Whittenton Branch. The portion of the Attleboro Secondary that would be used for the Whittenton Alternatives and the siting of the proposed traction power facility in Taunton (Electric Alternative only) would not require property acquisitions from communities that have been identified as having high concentrations of environmental justice populations. Therefore, no adverse impacts to residencies, community facilities, and businesses owned or staffed by environmental justice populations would result.

Stations

No property acquisition impacts in environmental justice areas would be required at the following stations: King's Highway, North Easton, Easton Village, Raynham Park, Taunton Depot, Taunton (Dean St.) and Canton Center Station. Stations with property acquisitions potentially affecting environmental justice areas are described below.

Stoughton—The proposed site of the relocated Stoughton Station is within an environmental justice neighborhood in Stoughton (Figure 4.4-13). The neighborhood meets environmental justice foreign-born criteria.

The relocated Stoughton Station would require acquisition of 7.44 acres of privately owned land. Three parcels would be obtained in entirety; 10 percent or less of three other parcels would be acquired. Two of these parcels may be eliminated as the project is further refined (Table 4.4-12 and Figure 4.4-13). No residential or community facility displacements would result from these acquisitions. Acquired parcels would be commercial and industrial in nature and have the potential to displace businesses.

Employees may be residents of the surrounding environmental justice neighborhoods. Job losses from these businesses would be expected and could adversely impact the surrounding environmental justice neighborhood. Adverse impacts to affected businesses may be offset should they be relocated within close proximity to their existing site. All acquisitions would be conducted in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (Uniform Act).

Table 4.4-12 Stoughton Station: Environmental Justice Property Acquisition

Municipality	Parcel Number	Ownership	Generalized Zoning	General Land Use	Environmental Justice Categories	Area (acres)
Stoughton	053-101	Private	Industrial	Industrial	Foreign-Born	1.05
Stoughton	053-102	Private	Industrial	Commercial	Foreign-Born	4.42
Stoughton	054-110	Private	Commercial	Commercial	Foreign-Born	0.04
Stoughton	054-401	Private	Commercial	Commercial (vacant)	Foreign-Born	0.01
Stoughton	054-406	Private	Industrial	Industrial	Foreign-Born	1.90
Stoughton	054-407	Private	Industrial	Undeveloped (residential)	Foreign-Born	0.02
	TOTAL					7.44

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various)
Shading denotes parcel takings that may be reduced or eliminated in final design.

Whale's Tooth—Portions of five parcels within an environmental justice neighborhood would be acquired for the Whale's Tooth Station, as listed in Table 4.4-13 and shown Figure 4.4-14.

Table 4.4-13 Whale's Tooth Station: Environmental Justice Property Acquisition

Municipality	Parcel Number	Ownership	Generalized Zoning	General Land Use	Environmental Justice Categories	Area (acres)
New Bedford	66-101	Public	Industrial	Industrial	Income, Minority	1.92
New Bedford	66-121[1]	Public	Industrial	Industrial	Income, Minority	0.38
New Bedford	66-133	Public	Industrial	Industrial	Income, Minority	3.38
New Bedford	66-133A	Private	Industrial	Industrial	Income, Minority	0.05
New Bedford	66-157	Public	Industrial	Industrial	Income, Minority	0.26
Total						5.99

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).
1 This parcel would be acquired for the train station (all rail alternatives).

Four of the parcels that would be acquired for the Whale's Tooth Station are publicly owned and one is privately owned. All are zoned for industrial purposes and the general land use is industrial and they are all currently used for transportation/utilities. None are used for residential purposes. MassDOT may lease, rather than acquire, publicly owned parcels from the City of New Bedford. All of the land would be used as a parking lot for the station. There would be no impacts to environmental justice populations because no residences or jobs would be lost.

Fall River Depot—Portions of four parcels within an environmental justice neighborhood would be acquired for the Fall River Depot Station, as listed in Table 4.4-14 and shown Figure 4.4-15. Another five parcels outside of the designated environmental justice neighborhood would also be acquired. All acquired parcels are privately owned and used for commercial or industrial purposes. Businesses that may need to be acquired include a flooring store (Jay Vee's Discount Flooring), electrical companies (GEMCO electrical contractors and Cotter Electrical), tire service shop (Jimmy's Used Tires), and automobile detail service (Auto Accent). Acquisition of these nine parcels would result in a property tax revenue loss of $40,411 for the City of Fall River or approximately 0.0006 percent of real estate tax revenues collected in fiscal year 2011.

No readily available information suggests that these businesses are owned by environmental justice populations. Employees may be residents of the surrounding environmental justice neighborhoods. Job losses from these businesses would be expected and could adversely impact the surrounding environmental justice neighborhood. Adverse impacts to affected businesses may be offset should they be relocated within close proximity to their existing site. All acquisitions would be conducted in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (Uniform Act).

Table 4.4-14 Fall River Depot Station: Environmental Justice Property Acquisition

Municipality	Parcel Number	Ownership	Generalized Zoning	General Land Use	Environmental Justice Categories	Area (acres)
Fall River	O-22-5	Private	Industrial	Commercial	Income, Minority	0.12
Fall River	O-22-6	Private	Industrial	Commercial	Income, Minority	0.10
Fall River	O-22-7	Private	Industrial	Commercial	Income, Minority	0.12
Fall River	O-22-11	Private	Industrial	Industrial	Income, Minority	0.47
Total						0.81

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

Battleship Cove Station—A portion of one parcel within an environmental justice neighborhood would be acquired for the Battleship Cove Station, as listed in Table 4.4-15 and shown in Figure 4.4-16.

Table 4.4-15 Battleship Cove Station: Environmental Justice Property Acquisition

Municipality	Parcel Number	Ownership	Generalized Zoning	General Land Use	Environmental Justice Categories	Area (acres)
Fall River	Y-1-3	Public	Industrial	Undeveloped	Income	0.08

Source: MassGIS 2002, 2005; municipal data 2009, aerial mapping, and online research (various).

The portion of the parcel that would be acquired for the Battleship Cove Station is owned by the City of Fall River and is part of the Ponta Delgada plaza. The land would be used for accessing the station platform. MassDOT may negotiate a lease arrangement with, rather than acquire from, the City for this parcel. There would be no impacts to the environmental justice population. No privately owned environmental justice neighborhood land would be acquired for constructing the Battleship Cove Station.

Layover Facilities

No parcels within an environmental justice neighborhood would be acquired for the Weaver's Cove East site layover facility. One parcel owned by the City of New Bedford would be affected by the Wamsutta site layover facility, but no privately owned environmental justice neighborhood land would be acquired (Figure 4.4-17). There would be no impacts to environmental justice populations due to property acquisitions from the layover facility sites because no residences or jobs would be lost.

Mitigation

In accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (Uniform Act), MassDOT would work with affected property owners to identify possible relocation sites. The same protocols would be followed for all property owners, regardless of designation. MassDOT will not mitigate other financial impacts or indirect displacement effects to environmental justice

neighborhoods that may result from property acquisition. Increased transit options and economic activity that may be induced by the South Coast Rail project has the potential to provide new employment opportunities for affected business owners and designated environmental justice populations in the area.

4.4.3.3 Socioeconomics

This section addresses neighborhood fragmentation and indirect socioeconomic effects related to transit-oriented development in the vicinity of stations.

Neighborhood Fragmentation

Southern Triangle (Common to All Rail Alternatives)

The Fall River Secondary and New Bedford Main Line segments are active freight railroads. Fragmentation of environmental justice neighborhoods, or any other neighborhoods, would not result from adding commuter rail service to the Fall River Secondary or New Bedford Main Line.

Stoughton Alternatives

The Stoughton Line between Canton and Stoughton is used as an active commuter railroad. Fragmentation of environmental justice neighborhoods, or any other neighborhoods, along this segment would not result from adding commuter rail service to the Stoughton Line.

South of the Stoughton Station, informal and unauthorized residential and recreational use of the railroad bed in several communities has established neighborhood continuity where none may have existed during the active phase of the railroad. Some neighborhood fragmentation may result in the segment between Stoughton Station and Weir Junction, but would not impact the environmental justice neighborhoods in Taunton. As described in Chapter 4.2, *Land Use*, the Stoughton Line in Taunton is adjacent to or passes through commercial, industrial, and residential development. The alignment crosses most residential neighborhoods perpendicular to main thoroughfares. Although temporary delays in traffic patterns may occur at road/railroad crossings, it is unlikely that the presence of the railroad in this segment would fragment the neighborhoods or disrupt continuity. Fragmentation of environmental justice neighborhoods would be negligible.

Whittenton Alternatives

The potential for neighborhood fragmentation under the Whittenton Alternatives along segments shared with the Stoughton Alternatives and along the Attleboro Secondary is negligible. Environmental justice neighborhoods are not located along the Whittenton Branch.

Indirect Effects of Transit-Oriented Development

As described in the *South Coast Rail Economic Development and Land Use Corridor Plan,*[14] transit-oriented development (TOD) in the vicinity of train stations would provide benefits to environmental justice populations. TOD emphasizes "compact, generally mixed-use development at or near transit

[14] EOT. 2009. *South Coast Rail Economic Development and Land Use Corridor Plan.* Commonwealth of Massachusetts, Executive Office of Transportation and Public Works, and Executive Office of Housing and Economic Development. Prepared by Goody Clancy, Inc.: Boston.

stops whose design encourages walking and transit use." Environmental justice populations generally have less access to automobiles than the statewide average; improved access to transit and jobs resulting from TOD would benefit these populations.

Environmental justice populations may also benefit from increased property values in the vicinity of station sites, and TOD could further amplify that effect. Conversely, property values may decrease along the alignments, due to negative impacts of increased noise from train operations. Near station sites there may also be a "gentrification" effect, a process whereby neighborhood revitalization or investment is accompanied by the influx of higher-income populations that displace lower-income residents in a community. Environmental justice populations (specifically, those defined as low income) are displaced from homes or apartments if property becomes unaffordable. The effects of gentrification may vary among property owners and renters. While owners may benefit from increased property values, renters may experience unaffordable rental increases. As described in the Corridor Plan, TOD may offset this effect if affordable housing is a required component.[15] Further discussion of potential property value impacts and a review of the relevant literatures is provided in Chapter 4.3, *Socioeconomics*. Overall, impacts to environmental justice populations due to property value changes are possible, but are too uncertain to predict precisely. Numerous factors other than transit contribute to changes in housing prices, such as the state of the national and regional economy, changes in income, inflation, tax policy and many other factors.

Because the impact is speculative and the mitigation measures are beyond the authority of USACE or MassDOT to implement, no mitigation for displacement/gentrification impacts is proposed. State and local programs that provide assistance to renters and home buyers at least partially offset impacts. Such programs include Section 8 housing programs, HomeBASE, Massachusetts Rental Vouchers, and the Alternative Housing Voucher Program, among others, as well as project based voucher plans like the Neighborhood Rental Initiative.[16] Additional tools are available to municipalities to minimize impacts of new transit service, such as programs to preserve affordable rental housing. Municipalities with stations in designated environmental Justice neighborhoods are Canton, Fall River, New Bedford, and Stoughton. A range of planning tools to address the potential adverse effects of establishing transit service in traditionally underserved communities, focusing on local agencies coordinating with state or regional agencies, is provided in *Maintaining Diversity in America's Transit-Rich Neighborhoods: Tools for Equitable Neighborhood Change* (Pollack et al, 2010). It would be the municipalities' responsibility to select and implement the appropriate tools.

Section 4.4.3.7 describes anticipated improvements in access to jobs, schools, and hospitals that would be experienced by communities—both designated and non-designated environmental justice neighborhoods—across the South Coast Rail corridor. It is anticipated that increased access to these services would help offset or mitigate minor and localized adverse impacts that may result from the South Coast Rail project.

Station-Level Indirect Effects

The following sections provide an overview of potential indirect socioeconomic changes in the vicinity of stations in environmental justice neighborhoods.

[15] Ibid.

[16] Commonwealth of Massachusetts. Executive Office of Housing and Economic Development. *Rental Assistance Management*. http://www.mass.gov/hed/housing/rental-assistance/.

Stoughton Station

While the relocated Stoughton Station would be sited within immediate proximity to the existing station, increased ridership along the line and the availability of new developable land near the station may encourage additional development in the area. While it is difficult to predict with any certainty how the introduction of the proposed station would affect the community, including environmental justice populations in the area (Figure 4.4-13), it is anticipated that because the area is already served by transit options that the relocation of the station would not induce development that would disproportionately and adversely affect environmental justice populations. Investment in and incentives for the area would be dependent on municipal goals, which may support smart growth and TOD that would help contain sprawl and support mixed-use development. Increased ridership would support new development in the area and would likely offer employment opportunities for environmental justice populations in the area. Because the proposed station site is located along an existing rail line, it is not anticipated that the South Coast Rail project would adversely affect community cohesion or fragment neighborhoods, including those in designated environmental justice neighborhoods.

King's Highway

The King's Highway Station site would not require development of an undeveloped area and has adequate infrastructure to serve the station and support nearby redevelopment. The site is near employment opportunities and environmental justice neighborhoods (Figure 4.4-5). The station could also help spur redevelopment on a nearby site currently occupied by an aging shopping plaza. The site presents an opportunity for joint development. This redevelopment opportunity could induce growth in nearby environmental justice neighborhoods.

Property values in environmental justice neighborhoods surrounding the King's Highway Station site may increase due to a perceived market value of residences or businesses close to a transit center. Additionally, TOD in the vicinity of the site could further enhance property values. Because of the undeveloped nature of the proposed station site and the availability of adjacent land, the introduction of the proposed station through redevelopment opportunities would likely introduce a certain amount of economic activity that may not otherwise occur. Such development, if properly planned, would help support community cohesion and would not fragment neighborhoods.

In New Bedford, 68.2 percent of the population is defined as living in environmental justice neighborhoods. The site is near (within 0.5 mile of) one neighborhood meeting environmental justice income criteria. Approximately 20.9 percent of the population (1,213 persons) within 0.5 mile of the King's Highway Station site resides in a designated environmental justice neighborhood. Neighborhoods meeting a full range of environmental justice criteria are outside of the 0.5-mile radius around the King's Highway Station site.

Approximately 21.7 percent of the households in New Bedford had no registered motor vehicles in 2000, compared to a statewide average of 12.7 percent. Based on these data, this portion of the New Bedford environmental justice populations in particular is likely to realize an improvement in local employment or access to transit services for employment and/or educational opportunities inside or outside the community.

Whale's Tooth

The Whale's Tooth Station site is located within and near environmental justice neighborhoods in New Bedford (Figure 4.4-6). This station may also serve environmental justice populations in nearby Fairhaven and Dartmouth.

The Whale's Tooth Station site would not require development in an undeveloped area and has adequate infrastructure to serve the station and support nearby redevelopment. The site is close to the New Bedford waterfront, downtown New Bedford, and the Hicks Logan redevelopment area. The station would be near employment opportunities and environmental justice populations. Immediately adjacent to the site are old mill buildings in the process of being converted to homes. The station could be used as a catalyst for TOD. The Hicks Logan area presents an opportunity to develop a mixed-use waterfront neighborhood that would be served by rail. This redevelopment opportunity could spur growth in nearby environmental justice neighborhoods.

Property values in environmental justice neighborhoods surrounding the Whale's Tooth Station site may increase due to a perceived market value of residences or businesses close to a transit center. Additionally, TOD in the vicinity of the site could further enhance property values. Because the proposed station site is located along an existing rail line, it is not anticipated that the South Coast Rail project would adversely affect community cohesion or fragment neighborhoods, including those in designated environmental justice neighborhoods. Such development, if properly planned, would help support community cohesion and would not fragment neighborhoods.

Statistical information suggests that environmental justice populations may benefit from the Whale's Tooth Station. In New Bedford, 68.2 percent of the population is defined as living in environmental justice neighborhoods. The site is within a neighborhood meeting environmental justice income and minority criteria, and is close to (within 0.5 mile of) other neighborhoods meeting foreign-born, minority, and/or income criteria. Approximately 85.6 percent of the population (8,937 persons) within 0.5 mile of the Whale's Tooth Station site resides in a designated environmental justice neighborhood.

Approximately 21.7 percent of the households in New Bedford had no registered motor vehicles in 2000, compared to a statewide average of 12.7 percent. Based on these data, this portion of the environmental justice population in New Bedford, in particular, may benefit from increased business activity in the area as well as transit services that would provide access to employment and/or educational opportunities outside the community.

The Whale's Tooth Station site is approximately 2 miles from downtown Fairhaven, where 9.7 percent of the population is defined as living in environmental justice neighborhoods (low income). It is approximately 4 miles from downtown Dartmouth, where 11.8 percent of the population is defined as living in environmental justice neighborhoods (foreign-born and/or income criteria). The data suggests that the environmental justice population in Fairhaven and Dartmouth, in particular, is likely to realize an improvement in access to transit services for employment and/or educational opportunities outside the community. Induced development around the proposed station may also provide new employment opportunities.

Fall River Depot

The Fall River Depot Station site is partially within and would therefore serve an environmental justice neighborhood in Fall River (Figure 4.4-8), and would also serve environmental justice populations in

nearby Swansea. The adjacent neighborhood meets environmental justice minority and low income criteria. The following subsections describe the direct and indirect impacts to environmental justice populations in Fall River and Swansea potentially resulting from constructing and using the Fall River Station along the Fall River Secondary.

The Fall River Depot Station site is located 1 mile north of downtown Fall River. It is within close proximity to a dense residential neighborhood and aging shopping plaza and across from the waterfront on Route 79, which is currently experiencing redevelopment. This site is close to employment opportunities and environmental justice neighborhoods. Through enhanced transit options, the station could help support redevelopment goals for the waterfront. Initiatives and incentives that are beyond the scope of this project would need to be implemented to ensure that all populations, including state-listed environmental justice populations, experience the benefits on increased transit and economic activity in the area that may be induced because of the South Coast Rail project. Such development, if properly planned, would help support community cohesion and would not fragment neighborhoods.

Statistical information suggests that the Fall River environmental justice populations may benefit from access to transit services at the Fall River Depot Station. As noted above, 57.3 percent of the Fall River population is defined as living in environmental justice neighborhoods. The site is close to (within 0.5 mile of) neighborhoods meeting environmental justice income and/or minority criteria. Approximately 50.2 percent of the population (4,652 persons) within 0.5 mile of the Fall River Station site resides in a designated environmental justice neighborhood. Neighborhoods meeting a full range of environmental justice criteria are near the Fall River Station site.

Approximately 20.7 percent of the households in Fall River had no registered motor vehicles in 2000, notably higher than the statewide average of 12.7 percent. Based on these data, this portion of the environmental justice population in Fall River is likely to realize an improvement in local employment and access to transit services to employment and/or educational opportunities both inside and outside the community. Induced development around the proposed station may also provide new employment opportunities.

The Fall River Depot Station site is approximately 4 miles from downtown Swansea, where 5.7 percent of the population is defined as living in environmental justice neighborhood (low income). Improved transit access to employment centers may provide new opportunities for environmental justice populations in Swansea. Induced development around the proposed station may also provide new employment opportunities.

Battleship Cove

The Battleship Cove Station site is in and near environmental justice neighborhoods in Fall River (Figure 4.4-9). The surrounding neighborhood meets low income criteria; nearby neighborhoods meet foreign-born, minority, income, and/or limited English proficiency criteria. The following subsections describe the direct and indirect impacts to the Fall River environmental justice populations potentially resulting from the construction and operation of the Battleship Cove Station along the Fall River Secondary Rail Segment.

The Battleship Cove Station site would be located on the Fall River waterfront, close to downtown, near the Fall River Heritage Park and other tourist attractions. The site is close to employment opportunities and environmental justice populations. Although the site is too small for redevelopment to occur right at

the station, the station could spur redevelopment in the waterfront area, a place with old manufacturing buildings and vacant land that the city would like to redevelop.

Property values in environmental justice neighborhoods surrounding the Battleship Cove Station site may increase due to a perceived market value of residences or businesses close to a transit center. Additionally, TOD in the vicinity of the site could further enhance property values. Through enhanced transit options, the station could help support redevelopment goals for the waterfront. Initiatives and incentives that are beyond the scope of this project would need to be implemented to ensure that all populations, including state-listed environmental justice populations, experience the benefits on increased transit and economic activity in the area that may be induced because of the South Coast Rail project. Such development, if properly planned, would help support community cohesion and would not fragment neighborhoods.

Statistical information suggests that the Fall River environmental justice populations may benefit from the Battleship Cove Station. In Fall River, 57.3 percent of the population is defined as living in environmental justice neighborhoods. The Battleship Cove Station site is within a neighborhood meeting environmental justice income criteria, and is close to (within 0.5 mile of) other neighborhoods meeting foreign-born, minority, income, and/or English language fluency criteria. Approximately 88.7 percent of the Fall River population (10,965 persons) within 0.5 mile of the Battleship Cove Station site resides in a designated environmental justice neighborhood.

Neighborhoods meeting a full range of environmental justice criteria are present outside of the 0.5-mile radius around the Battleship Cove Station site. Approximately 20.7 percent of the households in Fall River had no registered motor vehicles in 2000, compared to a statewide average of 12.7 percent. Based on these data, this portion of the environmental justice populations in Fall River may realize an improvement in local employment and/or educational opportunities both inside and outside the community due to improved options for transit access. However, the populations' choice to utilize the rail service is subject to individual factors, such as the commuter cost of the new rail service, as well as the income and availability of job opportunities inside and outside the community. Further discussion of potential local economic impacts and a review of the relevant literatures is provided in Chapter 4.3, *Socioeconomics*.

Taunton Depot

The Taunton Depot Station site is not within an environmental justice neighborhood (Figure 4.4-1a), but environmental justice neighborhoods are present in nearby Taunton.

The Taunton Depot Station site has adequate infrastructure to serve the station and support redevelopment. It is located close to employment opportunities and services as well as multi-family housing. The station would be near a key highway junction for Freetown, Berkley, and Lakeville. The use of this site could be a catalyst for TOD in that it offers an opportunity in the future to redevelop the existing shopping center into a mixed-use neighborhood or lifestyle center. The distance of this site from environmental justice neighborhoods limits the potential growth-inducing effects that this station may have on those neighborhoods. However, increased economic activity in the station area as a result of the proposed station and redevelopment initiatives may offer new employment opportunities for environmental justice populations.

As noted above, no environmental justice neighborhoods are present within 0.5 mile of the Taunton Depot Station site. Statistical information suggests that the Taunton environmental justice population

may benefit from access to transit services at the Taunton Depot Station. The site is approximately 2.25 miles from downtown Taunton, where 12.7 percent of the population is defined as living in environmental justice neighborhoods. These neighborhoods are identified as meeting minority and/or income environmental justice criteria.

Only 9.3 percent of the households in Taunton had no registered motor vehicles in 2000, compared to a statewide average of 12.7 percent. Based on these data, this portion of the environmental justice population in Taunton in particular is likely to realize an improvement in local employment and access to transit services for employment and/or educational opportunities outside the community.

Canton Center

The Canton Center Station is in an environmental justice neighborhood in Canton (Figure 4.4-3a). The neighborhood meets environmental justice minority criteria. Given the current active status of the Canton Center Station in a developed area of Canton, it is unlikely that direct or indirect effects to environmental justice populations would result from using this station.

Taunton (Dean Street) Station – Stoughton Alternatives

The Taunton Station site is located near, but not within, an environmental justice neighborhood in Taunton (Figure 4.4-3e). The nearby environmental justice neighborhood meets low income criteria.

The Taunton (Dean Street) Station site would not require development in an undeveloped area and has adequate infrastructure to serve the station and support nearby redevelopment. The site is near downtown Taunton, close to employment opportunities and near environmental justice neighborhoods. Enhanced transit options may help support redevelopment efforts. Initiatives and incentives that are beyond the scope of this project would need to be implemented to ensure that all populations, including state-listed environmental justice populations, experience the benefits on increased transit and economic activity in the area that may be induced because of the South Coast Rail project. Such development, if properly planned, would help support community cohesion and would not fragment neighborhoods.

Dana Street – Whittenton Alternatives

The Dana Street Station is not located in an environmental justice neighborhood, but a designated environmental justice area for the income and minority criteria is located adjacent to the site and several other environmental justice areas are designated in nearby downtown Taunton (Figure 4.4-4).

The station could also catalyze TOD and presents an opportunity to spur economic growth in Taunton. This redevelopment opportunity could spur growth in the surrounding environmental justice neighborhoods.

Property values in environmental justice neighborhoods surrounding the Dana Street Station site may increase due to a perceived market value of residences or businesses close to a transit center. Additionally, TOD in the vicinity of the site could further enhance property values.

Statistical information suggests that environmental justice populations may benefit from the Dana Street Station. Approximately 27.7 percent of the population (411 persons) within 0.5 mile of the Dana

Street Station site resides in a designated environmental justice area. Approximately 21.1 percent of the population of Taunton is defined as living in environmental justice areas.

Only 9.3 percent of the households in Taunton had no registered motor vehicles in 2000, compared to a statewide average of 12.7 percent. Based on these data, the this portion of the environmental justice population in Taunton in particular is likely realize an improvement in local employment and access to transit services for employment and/or educational opportunities both inside and outside the community.

4.4.3.4 Noise

Stoughton Alternatives

The Stoughton Alternatives pass through or near residential environmental justice neighborhoods in Stoughton, Taunton, New Bedford, and Fall River. These environmental justice neighborhoods would experience similar impacts under both the Stoughton Electric and Diesel Build Alternatives.

Noise impacts from the Stoughton Electric Alternative to environmental justice and non-environmental justice neighborhoods in communities through which it passes are listed in Table 4.4-16 and shown in Figures 4.4-18a-d, 4.4-19, and 4.4-20a-d.

Table 4.4-16 Stoughton Electric Alternative: Summary of Noise Impacts[1]

	Affected Residences within Environmental Justice Neighborhoods	Affected Residences within Non-Environmental Justice Neighborhoods	Total Affected Residences	Percent of Affected Residences within Environmental Justice Neighborhoods
Stoughton	7	98	105	6.7
Easton	0	322	322	0.0
Raynham	0	86	86	0.0
Taunton	21	72	93	22.6
Berkley	0	55	55	0.0
Lakeville	0	35	35	0.0
Freetown	0	99	99	0.0
New Bedford	41	114	155	26.5
Fall River	292	204	496	58.9
TOTAL	361	1,085	1,446	25.0

1 Values based upon a combination of train operational noise and horn use at crossings.

The noise analysis concluded that the electric train alternative along the Stoughton line would result in noise impacts (combined moderate and severe) to 1,446 residences. The number of impacted environmental justice neighborhood residences (361) is 25.0 percent of the total, while the number of noise-impacted non-environmental justice neighborhood residences (1,085) is 75.0 percent of the total.

Whittenton Alternatives

Noise impacts from the Whittenton Electric Alternative to environmental justice and non-environmental justice neighborhoods in communities through which it passes are listed in Table 4.4-17. These

environmental justice neighborhoods would experience similar impacts under both the Whittenton Electric and Diesel Build Alternatives.

Table 4.4-17 Whittenton Electric Alternative: Summary of Noise Impacts[1]

	Affected Residences within Environmental Justice Neighborhoods	Affected Residences within Non-Environmental Justice Neighborhoods	Total Affected Residences	Percent of Affected Residences within Environmental Justice Neighborhoods
Berkley	0	55	55	0.0
Easton	0	322	322	0.0
Fall River	292	204	496	58.9
Freetown	0	99	99	0.0
Lakeville	0	35	35	0.0
New Bedford	41	114	155	26.5
Raynham	0	86	86	0.0
Stoughton	7	98	105	6.7
Taunton	502	932	1,434	35.0
TOTAL	**842**	**1,945**	**2,787**	**30.2**

1 Values based upon a combination of train operational noise and horn use at crossings.

The noise analysis concluded that the Whittenton Electric Alternative trains would result in noise impacts (combined moderate and severe) to 2,787 residences. The number of impacted environmental justice neighborhood residences (842) is 30.2 percent of the total, while the number of noise-impacted non-environmental justice neighborhood residences (1,945) is 69.8 percent of the total.

Fall River

The Fall River Secondary, common to all rail alternatives, passes through or near state-listed environmental justice neighborhoods in Fall River. The current sound environment along this segment of the Fall River Secondary includes the active freight use of the railroad, heavy traffic on several major highways (Routes 6, 79, and 138, and I-195), and industrial and commercial activities. Noise impacts from the Fall River Secondary Rail Segment that would be experienced by both designated and non-designated environmental justice communities through which the railroad passes are shown in Figures 4.4-18a-d. In Fall River, environmental justice neighborhood residences impacted by noise would account for 58.9 percent of the total number of impacted residences by the Stoughton Electric Alternative; likewise, 58.9 percent of the total number of residences impacted by the Whittenton Electric Alternative would be environmental justice neighborhood residences.

New Bedford

The New Bedford Main Line Rail Segment, also common to all alternatives, passes through or near residential environmental justice neighborhoods in New Bedford. Noise impacts from the New Bedford Main Line to environmental justice and non-environmental justice neighborhoods in communities through which the railroad passes are shown in Figure 4.4-19. In New Bedford, environmental justice neighborhood residences impacted by noise from the Stoughton Electric Alternative would account for 26.5 of all impacted residences; likewise, the Whittenton Electric Alternative would impact 26.5 environmental justice neighborhood residences of all impacted residences.

Taunton

The current sound environment along the Taunton segment of the alignment includes the active freight use of the New Bedford Main Line and Attleboro Secondary through Weir Junction, heavy traffic on one major highway (Route 138), and industrial and commercial activities. In Taunton, environmental justice neighborhood residences that would experience noise impacts from the Stoughton Electric Alternative would account for 22.6 percent of the total number of impacted residences; 35.0 percent of total residences impacted by the Whittenton Electric Alternative would be environmental justice neighborhood residences.

Stoughton

The current sound environment in Stoughton includes the active commuter rail use of the Stoughton Line, and industrial and commercial activities. In Stoughton, environmental justice neighborhood residences impacted by noise would account for 16.7 percent of the total number of impacted residences by the Stoughton Electric Alternative; 6.7 percent of the total number of residences impacted by the Whittenton Electric Alternative would be environmental justice neighborhood residences.

Berkley, Easton, Freetown, Lakeville and Raynham

There are no environmental justice neighborhoods (as defined by the criteria cited in Section 4.4.1) along the Stoughton or Whittenton Electric Alternative in Berkley, Easton, Freetown, Lakeville, or Raynham; accordingly, there are no noise impacts to environmental justice neighborhoods in these communities.

Mitigation

Noise mitigation policy and process are described in detail in Chapter 4.6, *Noise*. In general, reasonable mitigation would be incorporated to address severe impacts. In areas where noise barriers are not cost-effective, alternative mitigation such as building sound insulation would be used. Two severely impacted sensitive receptor areas within designated environmental justice neighborhoods that meet MBTA's policy for a noise barrier:

- Murray Street area from Brightman Street to Cory Street in Fall River; and
- Almy Street area from Cory Street to President Avenue in Fall River.

The implementation of the proposed noise barriers would mitigate severe impacts to 36 sensitive receptors in designated environmental justice neighborhoods. The southernmost extent of the barriers, the one-block segment from Brownell Street to President Avenue on both sides of the Fall River Secondary, is beyond the boundary of the designated environmental justice neighborhood.

For the remaining severely impacted sensitive receptor locations, building insulation is the most cost-effective noise mitigation for reducing the noise impacts associated with rail operations. Building insulation would mitigate severe impacts to 38 sensitive noise receptors in designated environmental justice neighborhoods. The implementation of this measure would occur in both designated and non-designated environmental justice neighborhoods.

In selecting mitigation measures to offset adverse impacts associated with increased noise levels in designated environmental justice communities, the affected property owners would be consulted and

permitted to identify preferred building noise mitigation measures for their property from a potential list of measures that would be provided by MBTA.

4.4.3.5 Vibration

The results of an updated vibration impact analysis for the Stoughton Alternatives is provided in Table 4.4-18. The table compares the vibration impacts prior to mitigation that would be experienced by environmental justice communities to those that would be experienced by non-environmental justice neighborhoods.

There would be approximately 50 more vibration impacts in environmental justice neighborhoods under the Whittenton Electric Alternative than the Stoughton Electric Alternative because of the impacts along the Attleboro Secondary through downtown Taunton. Vibration impacts under the Stoughton and Whittenton Diesel Alternatives would be the same as the corresponding electric alternative.

Table 4.4-18 Stoughton Alternatives Vibration Impacts

	Vibration Impacts to Residential Receptors		
Municipality	**Environmental Justice Neighborhoods**	**Non-Environmental Justice Neighborhoods**	**Total**
Stoughton	0	22	22
Easton	0	76	76
Raynham	0	34	34
Taunton	10	36	46
Berkley	0	20	20
Lakeville	0	7	7
Freetown	0	31	31
New Bedford	0	10	10
Fall River	76	47	123
Total	**86**	**283**	**369**

Table 4.4-18 shows that the combined total number of residences impacted by vibration from the Stoughton Alternative's trains prior to mitigation would be 369. Environmental justice neighborhoods contain only 23 percent of the impacted sensitive receptors, while non-environmental justice neighborhoods contain 77 percent of the impacted sensitive receptors. Based on these proportions, the Stoughton Alternatives would not result in disproportionate vibration impacts when considering the alignment as a whole. However, the potential for disproportionate vibration impacts exists at the local level in Fall River where 62 percent of impacts would occur in environmental justice communities.

For the Whittenton Alternatives, approximately 25 percent of the total vibration impacts (105 out of 417) would be borne by environmental justice communities (specifically in Taunton and Fall River). For the overall alignment, this would not result in disproportionate vibration impacts to environmental justice communities. However, as with the Stoughton Alternatives, the Whittenton Alternatives would have the potential for disproportionate adverse vibration impacts in Fall River. In addition, the Whittenton Alternatives would have the potential for disproportionate adverse vibration impacts to environmental justice areas in Taunton (along the Attleboro Secondary). With incorporation of mitigation measures, the majority of vibration impacts would be eliminated and no disproportionate adverse impacts would occur. Vibration impacts to environmental justice and non-environmental justice

neighborhoods would be mitigated under either the Stoughton or Whittenton Alternatives, as summarized below.

Several vibration mitigation measures were assumed to be incorporated in the project design, including:

- Continuously welded rail
- Ballast and sub-ballast would be placed to standard depths to reduce transmission of vibration to the ground
- Turnouts would be located at least 100 feet away from sensitive receptors
- Trains and track would be maintained to minimize vibration generated by the trains

Additional mitigation measures to be determined during final design would include ballast mats (rubber mats placed under the ballast). Ballast mats would be provided where vibration mitigation is justified and soil conditions are appropriate. A detailed evaluation of the source-receiver soil conditions would be required during final design to assess the effectiveness of the ballast mat at impacted receptor locations along the corridor. Ballast mats were considered cost effective to offset vibration impacts at the 39 locations shown on Figures 4.4-18a-d, 4.4-19 and 4.4-20a-d. Under the Stoughton Alternatives, mitigation measures for 55 impacted residential receptors would be within designated environmental justice neighborhoods in Taunton and Fall River. Table 4.4-19 lists the proposed location of ballast mats in environmental justice neighborhoods in Taunton and Fall River. It is anticipated that the implementation of appropriate mitigation measures would offset vibration impacts borne by both designated and non-designated environmental justice communities throughout the South Coast Rail corridor.

The same types of mitigation measures noted above for the Stoughton Alternatives could be used to mitigate the vibration impacts specific to the Attleboro Secondary in Taunton.

Table 4.4-19 Stoughton Alternatives, Proposed Ballast Mat Locations in Environmental Justice Neighborhoods

Municipality	Number of Receptors within Designated Environmental Justice Areas
Taunton	
High Street/Paul Bunker Drive	6
Ingell Street	2
Fall River	
Cory Street	27
Durfee Street/Cedar Street	20
Total	55

4.4.3.6 Public Safety

As discussed in Chapter 4.1, *Transportation*, there would not be any significant impact to public safety and therefore environmental justice neighborhoods would not be disproportionately impacted from an at-grade crossing and public safety perspective.

Outreach materials including those available from Operation Lifesaver – a nationwide, non-profit public information program that promotes highway-rail grade crossing safety – would be available in English, Spanish, Portuguese, French creole, and French, to ensure that all populations, including those with limited English proficiency are informed about the South Coast Rail project and possible safety risks.

4.4.3.7 Access and Travel Time Impacts

This section describes the impacts to access and travel time that would be realized by environmental justice populations as a result of the South Coast Rail project.[17] This includes evaluation of the improvements in access to employment centers, and colleges and hospitals, as well as improvements in travel time to Boston from Taunton, Fall River, and New Bedford for both environmental justice and non-environmental justice populations (Appendix 4.4-A).

Each travel scenario was compared to the No-Build Alternative (Enhanced Bus) on a percent change basis, and results are provided for both environmental justice and non-environmental justice neighborhoods.

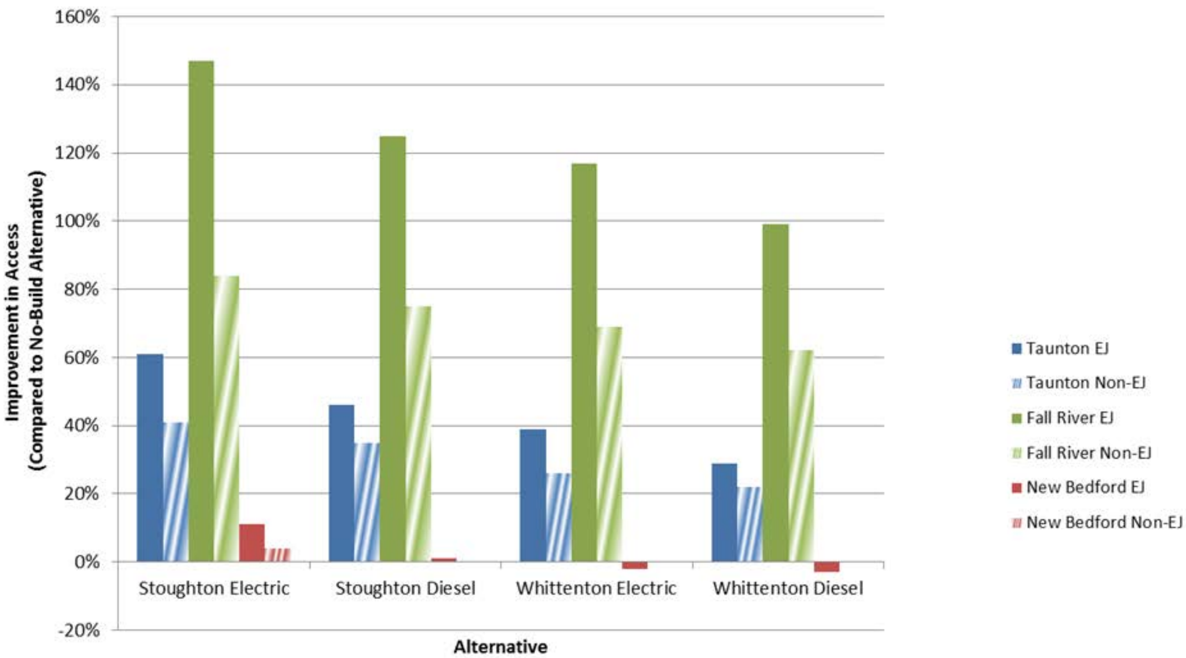
Potential Effects on Job Access

The South Coast Rail project would improve access to jobs for both environmental justice and non-environmental justice populations. The CTPS report identifies the relative improvements for each of the Build Alternatives as compared to the No-Build Alternative in transit access to employment opportunities from environmental justice and non-environmental justice neighborhoods in Taunton, Fall River, and New Bedford to jobs within 90 minutes' travel time.

Selected job access data are presented graphically in Figure 4.4-21. The relative improvement in access to basic jobs for environmental justice populations in the three communities is shown for each alternative as compared to the No-Build Alternative. The transit access percentages represent the change in the number of jobs that would be accessible within 90 minutes of these communities in reference to the No-Build Alternative. These values reflect a given population's change in the capacity to travel farther (to employment sites) within a 90-minute radius, as a result of changes in access to transit, from neighborhoods in each of the communities. Positive values represent improvements in access (more jobs accessible), while negative values represent degradations in access (fewer jobs accessible). Negative values are possible if a population (whether environmental justice or non-environmental justice) would realize less of a benefit by using a particular alternative than by using the Enhanced Bus system of the No-Build Alternative.

[17] CTPS. 2009. South Coast Rail Environmental Justice Study. Central Transportation Planning Staff, Boston Metropolitan Planning Organization: Boston.

Figure 4.4-21 Improvements in Job Access



These data suggest that, on average, access for environmental justice populations to basic jobs resulting from any of the South Coast Rail alternatives would be improved over the No-Build Alternative. The changes in access to basic jobs realized by environmental justice populations in the three communities vary considerably by alternative with the greatest improvements seen by Fall River populations using any of the alternatives. New Bedford populations would experience the least overall improvement. For New Bedford residents using the either of the Whittenton Alternatives, access to basic jobs would not be improved over the No-Build Alternative. The greatest average improvement would be accomplished by the Stoughton Electric Alternative where access to basic jobs for environmental justice populations in the three communities would improve by an average of 73 percent.

Potential Changes in Access to Colleges and Hospitals

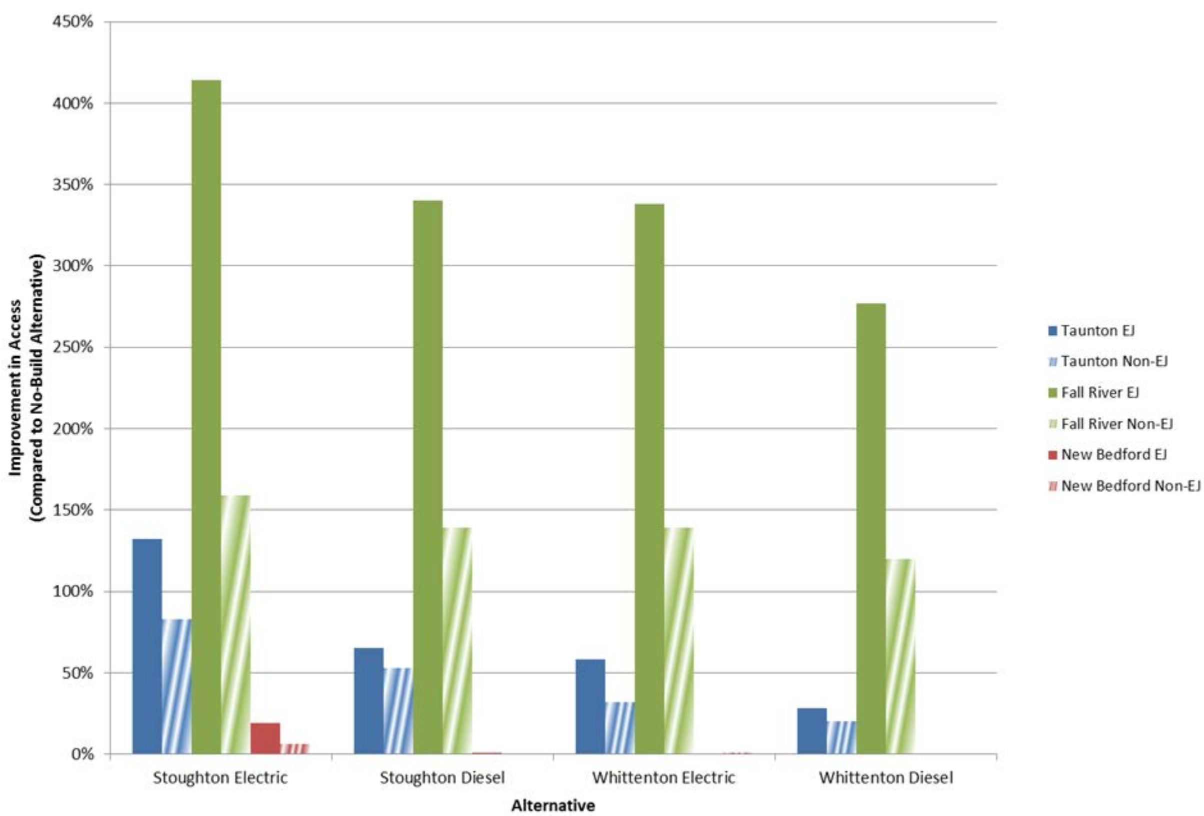
The South Coast Rail alternatives would result in improved access to colleges and hospitals for environmental justice and non-environmental justice populations. The CTPS report indicates that the project would improve transit access to higher education (i.e. commutation access to college enrollment slots) and non-emergency medical facilities (i.e. "hospital beds") for both environmental justice and non-environmental justice populations. The CTPS report identifies the relative improvements in transit access for each of the Build Alternatives as compared to the No-Build Alternative as reflected in the increase in the number of colleges and hospitals within 90 minutes' travel time by transit from environmental justice and non-environmental justice neighborhoods in Taunton, Fall River, and New Bedford.

Hospital access data are presented graphically in Figure 4.4-22. The relative improvement in access to hospitals for environmental justice populations in the three communities is shown for each alternative as compared to the No-Build Alternative. The transit access percentages represent the change in the number of medical facilities (as expressed in the total number of hospital beds) that are within the 90-

minute travel time radius. As with the access to basic jobs data described above, these values reflect a given population's change in the capacity to travel farther (to hospitals) within a 90-minute radius, as a result of changes in access to transit, from neighborhoods in each of the communities.

These data suggest that, on average, access for environmental justice populations to hospitals resulting from any of the South Coast Rail alternatives would be improved over the No-Build Alternative. The changes realized by environmental justice populations in the three communities vary considerably, again with the greatest improvements in access to hospitals seen by environmental justice populations in Fall River under any alternative. The least improvement would be seen by New Bedford populations using any alternative. CTPS attributes these minimal improvements to station locations (such as Whale's Tooth Station) that do not directly connect with existing Southeastern Regional Transit Authority bus terminals in New Bedford.

Figure 4.4-22 Improvements in Access to Hospitals



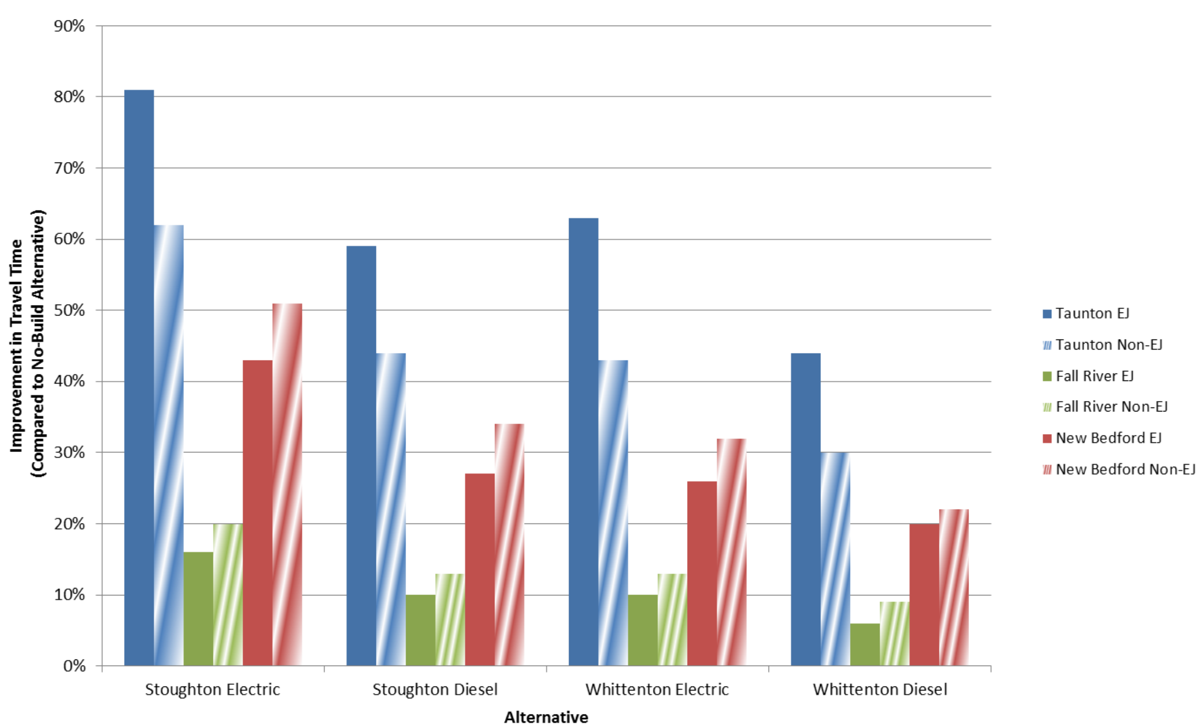
Potential Effects on In-Vehicle Travel Time to Boston

The South Coast Rail project would also result in improved as compared to the No-Build (Enhanced Bus) Alternative travel times to Boston from three South Coast communities for environmental justice and non-environmental justice populations. All alternatives would reduce in-vehicle travel times from the three communities to a selected location (South Station) in Boston for both environmental justice and non-environmental justice populations. Figure 4.4-23 graphically presents the relative improvements for each of the Build Alternatives as compared to the No-Build Alternative in travel time from environmental justice and non-environmental justice neighborhoods in Taunton, Fall River, and New Bedford to South Station.

These data suggest that, on average, travel times to Boston for environmental justice populations would decrease as compared to the No-Build Alternative as a result of any of the Build Alternatives proposed for the South Coast Rail project. The changes realized by environmental justice populations in the three communities vary moderately with environmental justice populations in Taunton experiencing the greatest benefit from all rail alternatives. Fall River populations (both environmental justice and non-environmental justice) would receive the least benefit from any of the Build Alternatives.

In some cases, the improvements for non-environmental justice populations are greater than for the environmental justice populations. This is a result of the relative locations of existing or proposed train stations in relationship to the environmental justice or non-environmental justice neighborhoods. None of the Build Alternatives would result in an increase of travel time from Taunton, Bedford or Fall River to Boston as compared to the No-Build Alternative for either environmental justice or non-environmental justice populations in these communities.

Figure 4.4-23 Improvements in Travel Time to Boston (South Station)



4.4.4 Summary of Impacts by Alternative

Table 4.4-20 summarizes potential adverse and beneficial effects to designated environmental justice communities that may result from the implementation of each alternative of the South Coast Rail project.

Table 4.4-20 Summary of Effects on Environmental Justice Populations

Effects	Stoughton Electric	Stoughton Diesel	Whittenton Electric	Whittenton Diesel
Adverse Effects				
Neighborhood Disruption/Fragmentation	None	None	None	None
Residential Displacements	None	None	None	None
Business/Job Displacements[1]	Minimal	Minimal	Minimal	Minimal
Noise Impacts in Environmental Justice Neighborhoods (number of residences impacted by moderate and severe increases in noise levels)[2]	361	361	842	842
Percent of Total Noise Impacts in Environmental Justice Neighborhoods	25%	25%	30%	30%
Vibration Impacts in Environmental Justice Neighborhoods (impacted sensitive receptors)[3]	86	86	105	105
Percent of Total Vibration Impacts in Environmental Justice Neighborhoods	23%	23%	25%	25%
Beneficial Effects (percent improvement compared to No-Build Alternative)				
Access to Jobs[4]				
Taunton	118	77	67	44
Fall River	187	151	140	113
New Bedford	21	4	-1	-2
Access to Colleges[5]	78	46	52	33
Access to Hospitals[6]	188	135	132	102
Travel Time to Boston[7]	47	32	33	23
Station Area TOD[8]	Yes	Yes	Yes	Yes

1 Business and job displacements would result from private property acquisition for the Fall River Depot Station, and would be minor as compared to the overall workforce in the surrounding community. See Chapter 4.2, *Land Use*, and Chapter 4.3, *Socioeconomics*.
2 Noise impacts data is based on the Stoughton and Whittenton Electric Alternatives; however the impacts of the diesel alternatives would be similar
3. Diesel and electric vibration impacts would be the same.
4. Provided as an average in improvement, as compared to the No-Build Alternative, in access to basic, service, and retail jobs within a 90-minute radius of each municipality. Source: CTPS 2009.
5 Provided as an average in improvement, as compared to the No-Build Alternative, in access from Taunton, Fall River, and New Bedford to colleges and hospitals. Source: CTPS 2009.
6 Provided as an average in improvement, as compared to the No-Build Alternative, in travel times from Taunton, Fall River, and New Bedford to Boston's South Station. Source: CTPS 2009.
7 Qualitative assessment of the potential for transit-oriented development in the vicinity of the station site that would benefit environmental justice populations. Source: Goody Clancy

Adverse effects to environmental justice populations that would result from the South Rail project are similar for all applicable resource topics with the exception of noise and vibration. Among the rail alternatives, the Whittenton Alternatives would impact the greatest number of residences, and the Stoughton Alternatives the least. Additionally, a greater percentage of noise impacts would be experienced by designated environmental justice populations under the Whittenton Alternatives than

the Stoughton Alternatives. Under all rail alternatives and on a regional level, adverse noise impacts would not be disproportionately borne by state-listed environmental justice communities. However, on the municipal level, the analysis concludes that state-listed environmental justice populations in Fall River would experience disproportionately high and adverse noise impacts as compared to non-environmental justice populations (prior to mitigation) under the Stoughton and Whittenton Alternatives.

Vibration impacts would be experienced across the region in both designated and non-designated environmental justice communities. Overall, adverse impacts would not be predominately borne by designated environmental justice communities under the Stoughton or Whittenton Alternatives. At the local level, designated environmental justice communities would experience a disproportionately high share of vibration impacts in Fall River under both the Stoughton and Whittenton Alternatives. Environmental justice communities in Taunton would experience a disproportionately high share of vibration impacts under the Whittenton Alternatives. Identified mitigation measures would be able to offset these impacts.

There are also benefits associated with the rail alternatives that would be recognized by all populations regardless of designation. Increased access would reduce travel times to Boston and other employment centers. Average travel time savings from Fall River, Taunton, and New Bedford greatest under the Stoughton Electric Alternative, followed by the Whittenton Alternative which would improve travel times by 14 percent. The Stoughton Electric also represents the greatest travel time savings to colleges and hospitals. The Whittenton Diesel Alternative typically represents the least travel time savings of the rail alternatives.

The beneficial effects to environmental justice populations that would result from the South Coast Rail project vary considerably by alternative and community. Property values in environmental justice neighborhoods near stations may increase as a result of improved access to transit and subsequent TOD. If property values get too high, environmental justice populations may be priced out of their current locations. Conversely, property values in environmental justice neighborhoods along the alternative alignments may decrease as a result of increased noise from train operations.

4.4.5 Public Outreach

In October 2008, project fliers inviting participation in planning activities were sent to more than 80 churches and community centers in environmental justice neighborhoods in New Bedford, Fall River, and the surrounding areas. A bilingual flier (English and Portuguese or English and Spanish) was distributed which invited residents to participate in public meetings on potential sites and development opportunities for rail stations in the New Bedford area. To better accommodate non-English speaking populations, all meeting notices offered translation services at public meetings.

In July 2009, a large-scale mailing was issued of a brochure with general project information in English, Spanish and Portuguese. The Southeastern Regional Planning and Economic Development District (SRPEDD) was consulted to further widen the outreach to environmental justice communities, including many of the same churches and community centers from the earlier mailing, as well as commissions on disability, housing authorities, councils on aging and newspapers such as the Cape Verdean News and the Portuguese Times, based in New Bedford. In addition, brochures were sent to the 31 public libraries and town planners in the region. In total, brochures were mailed to 250 recipients.

Planning and economic development staff and elected officials (including mayors) in New Bedford, Fall River and Taunton (and all of the other South Coast communities which may host stations) were consulted to gather ideas on economic development, sustainability and smart growth related to the project. These leaders and SRPEDD work with environmental justice groups in the communities on a regular basis, facilitating coordination with the public outreach team. The direct approaches have been through the community workshops on stations (one each in Fall River and Taunton and two in New Bedford).

In addition, MassDOT's South Coast Rail website has been maintained and updates are made as necessary. The website provides access to technical reports, fact sheets, flyers, and project updates. Targeted outreach efforts would be undertaken prior to public meetings and other outreach activities. Meeting notices would continue to be provided in foreign languages (Portuguese and Spanish) and translation services at meetings and for technical documents would continue to be provided upon request. Project staff would continue to meet with churches, community groups, and other organizations to engage environmental justice populations in the decision-making process.

In selecting mitigation measures to offset adverse impacts associated with increased noise levels in designated environmental justice communities, affected property owners would be consulted.

4.5 VISUAL AND AESTHETIC RESOURCES

4.5.1 Introduction

This chapter describes the visual character and aesthetic resources within and adjacent to the South Coast Rail Alternatives and identifies the effects to visual and aesthetic resources that may result from implementing each of the proposed South Coast Rail alternatives (including railroad or highway alignments, train or bus stations, and layover facilities).

Section 4.5.1 provides general information relative to the visual and aesthetic resources and associated regulations. Section 4.5.2 identifies and describes the specific viewpoints where elements of the rail corridor are, or may be, visible by the public and where adverse or beneficial impacts could occur. Sections 4.5.3 and 4.5.4 identify any changes in the visual setting that could have adverse impacts on the visual and scenic resources of importance to residents. Section 4.5.5 presents mitigation measures to minimize the visual impact of the project alternatives, and Section 4.5.6 outlines the regulatory compliance requirements for visual and aesthetic resources.

The Secretary of the Executive Office of EEA[1] issued a Certificate on the ENF on April 3, 2009. No specific requirements for evaluation of visual and aesthetic resources are included in the Certificate.

The Secretary's Certificate on the DEIR, dated June 29, 2011, included the following requirements in regard to National Wild and Scenic River resources:

- "*Taunton Wild and Scenic River*. The FEIR should include an update on consultations with the National Park Service regarding the status of Taunton River as a National Wild and Scenic River, and to discuss issues relating to water quality impacts from construction and stormwater runoff, rail line crossings of the Taunton and its tributaries, impacts to natural and cultural landscape features, selection and siting of layover facilities, and construction of the Fall River Depot station."

4.5.1.1 Resource Definition

Visual and aesthetic resources are defined as the features or stimuli within the landscape and the values attached to those resources by the viewer upon which a visual experience is based. General visual elements of a rail line include:

- Crossing protection systems;
  - gates
  - pole mounted flashers
  - flashers on cantilevers
- Overhead railroad bridges crossing roads, water bodies or other natural features;
- At-grade road crossings (the rails);

[1] Formerly, the Executive Office of Environmental Affairs.

- Overhead catenary;
- Vegetation along right-of-way;
- Stations and/or platforms, parking and buildings; and
- Lighting at stations.

4.5.1.2 Regulatory Context

There are no state or federal regulations applicable to the evaluation of aesthetics and visual resources. The CEQ NEPA regulations do require that an EIS evaluate a proposed action's impact on "urban quality, historic and cultural resources, and the design of the built environment."[2]

4.5.1.3 Methodology

Views of potential project elements are observed and described from public viewpoints, based upon a pedestrian at street level. Existing viewpoints of project elements include:

- Views of each proposed station from the nearest public way;
- Views of proposed grade-separated crossings; and
- Views of the rail right-of-way from selected public viewpoints.

Viewpoints were selected based on an understanding of the proposed alternative alignments and station sites and the location's visibility from a public right-of-way. Field reconnaissance confirmed viewpoints and photographs were taken from each location. Each viewpoint is shown on a map, described in text, and documented with a photograph.

4.5.2 Existing Conditions

This section identifies and describes specific viewpoints where elements of the rail or highway corridor are, or may be, visible by the public and where adverse or beneficial impacts could occur. These viewpoints are identified and described below and depicted in Figures 4.5-1 through 4.5-29. Viewpoints are identified with a number that corresponds to the figures.[3]

4.5.2.1 Regional Context

The majority of the study area is an existing rail corridor or highway, some of which is inactive. As discussed in Chapter 4.2, *Land Use and Zoning*, these areas consist of a range of single-family and multi-family residences, and commercial, industrial and mixed-use buildings. The predominant land uses visible from the corridor are residential, natural resources (forest and other protected undeveloped land), and industrial or commercial centers of activity. The uses along the rail corridor vary depending on the location relative to urbanized centers.

[2] Council on Environmental Quality. 2009. Code of Federal Regulations (CFR), Title 40: Protection of the Environment, Part 1502-Environmental Impact Statement, Section 16(g) Environmental Consequences (40 CFR 1502.16(g)).

[3] The viewpoints, numbered to coincide with the alternatives discussion (Southern Triangle, the Stoughton Alternatives, and the Whittenton Alternatives), are described generally north to south, east to west. Stations are numbered as they occur along each alignment. Viewpoint numbers are nonconsecutive.

Natural visual resources around the Project Area consist mostly of the open space resources discussed in Chapter 4.10, *Protected Open Space and Areas of Critical Environmental Concern*, and Chapter 4.16, *Wetlands.* These natural resources include ACECs, conservation land, wetland systems, and areas of important biodiversity value such as Hockomock Swamp, Pine Swamp, Assonet Cedar Swamp, Acushnet Cedar Swamp, Fowl Meadow and Ponkapoag Bog, and Forge Pond. Open space within view of the proposed rail corridors also includes passive and active recreation facilities such as Turner Playground, North Park, Freetown-Fall River State Forest, Stoughton Memorial Conservation Land, Ricker Field, Memorial Park, and municipal fields.

4.5.2.2 Existing Conditions within the Study Corridor

Southern Triangle (Common to all Build Alternatives)

This section describes typical (or representative) views of the New Bedford Main Line or the Fall River Secondary corridors from public streets. The New Bedford Main Line and the Fall River Secondary corridors are existing and active rail lines carrying freight. Tracks are visible primarily from cross-streets, where the general elements of rail lines are visible. Along these rail corridors, the primarily visible elements are crossing gates and lights.

Right-of-Way from Malbone Street (No. 1)

The right-of-way and grade crossing of the New Bedford Main Line at Malbone Street in Lakeville is characterized by pole-mounted flashers on either side of the right-of-way (Figure 4.5-1). There are no crossing protection gates or cantilevered flashers.[4] At this viewpoint, Malbone Street is a narrow, two-lane roadway bordered by forest and low-density single-family residential land uses. The viewpoint was selected because of its location on a residential roadway and for the potential impacts of improving the grade crossing.

Right-of-Way from Samuel Barnet Boulevard (No. 2)

The right-of-way and grade crossing of the New Bedford Main Line at Samuel Barnet Boulevard in New Bedford is characterized by flashers on either side of the right-of-way and a gated access way along the right-of-way (Figure 4.5-2). The flashers are both pole-mounted and cantilevered over the roadway. Samuel Barnet Boulevard is a two-lane road with ample shoulders on either side and is forested at this viewpoint. The viewpoint was selected because of its location on a forested roadway and for the potential impacts of improving the grade crossing.

Grade Crossing from Tarkiln Hill Road and King's Highway (Nos. 3, 4, 5)

Shown from three viewpoints (Figure 4.5-3), the grade crossing of the New Bedford Main Line at Tarkiln Hill Road and King's Highway in New Bedford is characterized by dual-side grade crossing protection gates and pole-mounted flashers. Tarkiln Hill Road and King's Highway are each two-lane roads that create a three-way intersection at the rail right-of-way. Together these roadways serve as a high-traffic commercial corridor. This intersection is surrounded by retail land uses. These viewpoints were selected because of the high-traffic nature of this roadway and the anticipated need to upgrade this grade crossing.

[4] A cantilevered flasher is a component of the grade crossing protection system that is suspended from a pole over the roadway. Flasher refers to the warning lights for automobiles.

Right-of-Way from Beechwood Road (No. 9)

The grade crossing of the Fall River Secondary at Beechwood Road in Freetown is characterized by pole-mounted crossing protection signs on either side of the right-of-way (Figure 4.5-4). The crossing at Beechwood Road currently does not have crossing protection flashers or gates. The view of the rail corridor from Beechwood Road is a long view of forest with track down the center. Beechwood Road is a rural, two-lane roadway surrounded primarily by forest at this viewpoint. The viewpoint was selected because of its location on a residential roadway and for the potential impacts of improving the grade crossing.

Stoughton Alternatives

This section describes typical (or representative) views of the Stoughton Line corridor from public streets. The Stoughton Alternatives (Electric and Diesel) would use the existing Stoughton Branch from Canton Junction to Weir Junction in Taunton. Portions of the Stoughton Line are currently inactive railroad rights-of-way. Evidence of a right-of-way is visible in some locations, primarily at cross-streets and where the right-of-way has been converted to driveways or paths. General elements of rail lines are not visible.

View of Right-of-Way from Route 138 (No. 20)

The Stoughton Line right-of-way was observed from Morton Street facing north, near the intersection with Route 138 in Stoughton (Figure 4.5-5). The right-of-way runs parallel to Route 138, which is characterized by low-density commercial retail and service establishments. A residential neighborhood exists on the west side of the right-of-way. The inactive rail right-of-way is visible in the street as it crosses Morton Street but is completely overgrown as it proceeds through the vegetated area between Route 138 and Morton Street. As this is currently an inactive right-of-way, there are no grade-crossing elements. The grade crossing is visible from Morton Street, immediately adjacent residences, and Route 138. The right-of-way is not visible. This viewpoint was selected because of the clearing on the right-of-way that would be required to accommodate the Stoughton Alternatives, grade crossing upgrades and potential views of the right-of-way from grade crossings.

Right-of-Way and Driveway from Fish and Game Club (No. 22)

The Stoughton Line right-of-way was observed from the driveway of the Stoughton Fish and Game Club on Route 138/Washington Street in Stoughton, facing east (Figure 4.5-6). The right-of-way runs parallel to Route 138, which is characterized by low-density commercial retail and service establishments. The Club is a private use, accessed from a short driveway off Route 138. The proposed right-of-way would cross this driveway. In its current condition, the right-of-way is vegetated and difficult to discern. This driveway is visible from the Fish and Game Club and from Route 138 at the driveway, due to the higher elevation of the roadway. This viewpoint was selected because of the clearing on the right-of-way that would be required to accommodate the Stoughton Alternatives and because the right-of-way crosses a driveway.

Easton Village Overpass at Main Street (No. 25)

The Main Street overpass in Easton was observed from a second angle, facing west along Main Street in Easton Village (Figure 4.5-7). This viewpoint shows a grade-separated rail crossing that is barely perceptible. Main Street passes over the rail right-of-way as a level roadway, with few features that indicate the presence of an overpass. On either side of Main Street, chain link fence marks the limits of

the overpass beyond the sidewalk. The right-of-way is overgrown, which also hinders its visibility from Main Street. Adjacent to the overpass, Main Street contains neighborhood commercial land uses, specifically small businesses in older buildings as well as a more recent gas station. This viewpoint was selected because the proposed project may require upgrades to the overpass and would require clearing of the right-of-way visible from the overpass.

Easton Village Right-of-Way under Main Street (No. 25)

The Stoughton Line right-of-way was observed from within the right-of-way south of the Main Street overpass in Easton Village (Figure 4.5-7). As it enters Easton Village, from the south, the Stoughton Line right-of-way is set below grade and would cross under Main Street and rise to the proposed Easton Village Station north of the town center. The right-of-way, which is somewhat overgrown, is flanked by a stone retaining wall on the west and a vegetated embankment on the east. At this location, surrounding uses include older residential homes to the east and the parking lot for a professional building to the west. The bridge is constructed of concrete, supporting a two-lane roadway. This viewpoint was selected because of the required overpass upgrades for operation of this alternative and potentially required right-of-way clearing.

Grade Crossing from Foundry Street (Nos. 27, 28)

The grade crossing of the Stoughton Line at Foundry Street in Easton was observed facing northeast and southwest (Figure 4.5-8). Both viewpoints show a right-of-way. This right-of-way is difficult to discern as a potential rail corridor, due to overgrown forest that extends to the edge of the road. Looking southeast, the right-of-way is beyond the Foundry Street crossing of the Black Brook Conservation Area. Looking northeast, the right-of-way is in the forefront of the photograph and marked by boulders on the south side of Foundry Street (left of photo). There are no indications of a grade crossing at this viewpoint. This viewpoint was selected because there is no visual evidence of an existing rail right-of-way or grade crossing; grade crossing upgrades and clearing would be required for the proposed project.

Right-of-Way from Bridge Street (No. 30)

The Stoughton Line right-of-way was observed from Bridge Street in Raynham, facing north (Figure 4.5-9). As the name indicates, Bridge Street passes over the right-of-way. From Bridge Street, the inactive rail right-of-way is clearly visible; it is flanked by power lines and beginning to become overgrown by the adjacent forest (a portion of the Hockomock Swamp ACEC). The center portion of the inactive rail right-of-way in the foreground is partially covered with ice and inundated. Snow and ice are accumulated along the right-of-way. This viewpoint was selected because of the views from Bridge Street and the clearing required for the right-of-way upgrades.

Right-of-Way at Carver Street (No. 31)

The Stoughton Line right-of-way and grade crossing at Carver Street was observed from the right-of-way south of Carver Street facing north (Figure 4.5-10). The right-of-way at this viewpoint is marked by log posts and rocks; it is in active use as a dirt roadway on either side of Carver Street. As this is an inactive right-of-way, there are no grade-crossing elements. This section of Carver Street is residential, but the right-of-way is primarily flanked by forest. This right-of-way is clearer of vegetation than other viewpoints along this segment of the Stoughton Line, although no tracks exist. This viewpoint was selected because the Stoughton Alternatives would introduce a grade crossing at this location.

Grade Crossing near Post Office on Route 138 (Nos. 32, 33, 34)

The proposed grade separation of the Stoughton Line at Washington Street/ Route 138 in Raynham was observed at three viewpoints (Figure 4.5-11). This proposed grade separation occurs adjacent to the intersection of the Stoughton Line with the Whittenton Branch. Route 138 is a high-traffic, two-lane commercial corridor. The development occurring near this viewpoint is low-scale commercial service and sales uses, typical of an older commercial corridor. Along the corridor, commercial properties are interspersed with forest. Generally, businesses in this stretch of Route 138 occupy one- or two-story older wooden buildings, with parking at the street edge. Beyond the commercial uses, there is a residential neighborhood east of Route 138 and forest to the west. These viewpoints were selected because of the proposed grade separation that would be required for the Route 138 crossing.

Viewpoints No. 33 and 34 were observed looking north and south on Route 138, respectively, where the Stoughton Line right-of-way crosses Route 138. As this is an inactive right-of-way, there are currently no grade-crossing elements and the right-of-way is difficult to discern. West of Route 138, in the north-facing photograph, the right-of-way is present north of the commercial plaza. East of Route 138, the right-of-way is not visible. Viewpoint No. 32 is of the intersection of the Stoughton Line with the Whittenton Branch, with Route 138 in the background.

Grade Crossing near King Philip Street, east of Route (No. 35)

This viewpoint of the grade crossing of the Stoughton Line was observed facing east on King Philip Street (east of Route 138) in Raynham (Figure 4.5-12). King Philip Street is a two-lane suburban roadway with no sidewalks or shoulder and a moderate curve at this viewpoint. The view along King Philip Street is forested and residential on both sides. As this is an inactive right-of-way, there are no grade-crossing elements. The right-of-way is difficult to discern; it is marked by log posts at either side of the road and can be found in the center of the photograph. The right-of-way itself has become a residential driveway on the north side of King Philip Street. This viewpoint was selected because the Stoughton Alternatives would introduce a grade crossing at this location.

Grade Crossing near East Brittania Street, Raynham (No. 35a)

This viewpoint of the grade crossing of the Stoughton Line was observed facing south crossing East Brittania Street in Raynham. The right-of-way portion in Pine Swamp is occupied by the overhead utility line in the foreground crossing East Brittania Street. The right-of-way then extends further south in a forested area vegetated area (Figure 4.5-13). East Brittania Street is a two-lane suburban roadway with no sidewalks or shoulder and relatively straight at this viewpoint. The view along East Brittania Street is forested on both sides. As this is an inactive right-of-way, there are no grade-crossing elements. The northern portion of the right-of-way is discernible from East Brittania Street looking north due to the clear cut vegetation maintenance for the overhead utility line, which cuts a visual corridor through Pine Swamp. The overhead utility line, however does not extend southward, across East Brittania Street. Unlike the northern portion of the right-of-way through Pine Swamp, the portion of the right-of-way extending south of East Brittania Street is not clear-cut and thus overgrown with mature trees. The right-of-way south of East Brittania Street is thus not easily discernible. This viewpoint was selected because the Stoughton Alternatives would introduce a grade crossing at this location.

Right-of-Way and Grade Crossing from Thrasher Street (Nos. 36, 37)

Two viewpoints of the Stoughton Line right-of-way and the grade crossing were taken from Thrasher Street in Taunton (Figure 4.5-14). Viewpoint 37 is south-facing, showing a wide, forested corridor sunken below surrounding grade flanking the right-of-way. The rolling nature and groundcover on the right-of-way in this location mask its former use as an operative railroad. The right-of-way is flanked by forest and, at Malcolm Circle in Taunton, by residences. The right-of-way north of Thrasher Street is less clear, as noted in the next viewpoint.

Viewpoint 36 is observed along Thrasher Street looking east towards the rail right-of-way. The view along Thrasher Street shows forest north of the roadway and residences to the south. To the south, the right-of-way is visible below street level, i.e., depressed relative to surrounding grade; Thrasher Street is a narrow, two-lane roadway with no shoulder or sidewalks and exhibits a sharp curve at this viewpoint. There are no guardrails. A row of boulders and wood and wire fencing, at the right of Viewpoint 36, act as barriers to access. There are currently no grade-crossing elements at this crossing, as it is not in active use. This viewpoint was selected because the Stoughton Alternatives would introduce a grade-separated crossing at this location, which is characterized by an already depressed right-of-way relative to surrounding grade.

Taunton River Bridges from Summer Street (No. 39)

Two rail bridges crossing the Taunton River are observed from this viewpoint taken from Summer Street/Route 140 looking north in Taunton (Figure 4.5-15). This viewpoint shows the forested corridor of the Stoughton Line heading north. The bridges are constructed of cement and wood. The bridges are constructed of wood on pilings. The water supply line shown on the two bridges is a recent addition to this viewpoint. This viewpoint was selected because the bridges would require upgrades.

Taunton River Bridge from Ingell Street (No. 40)

The New Bedford Main Line crosses the Taunton River just south of the intersection of the Attleboro Secondary and Stoughton Line in Taunton (Figure 4.5-16). This viewpoint is of the forested rail corridor and one of the bridges that cross the Taunton River. The bridge was viewed from the right-of-way southeast of the Taunton Department of Public Works yard on Ingell Street. This bridge is constructed of wood on pilings. The viewpoint was selected for its potential to be viewed by the public from the Taunton River and because the bridge may require upgrades as part of the Stoughton Alternatives.

Whittenton Alternatives

This section describes typical (or representative) views of the Whittenton Branch corridor from public streets. The Whittenton Alternatives, which would use the Whittenton Branch of the Stoughton Route, would avoid construction through the Pine Swamp by restoring service to the Whittenton Branch rail line. The Whittenton Alternatives diverge from the Stoughton Line at Raynham Junction and connect to the New Bedford Main Line at Whittenton Junction in Taunton. The entire Whittenton Branch is currently an inactive railroad right-of-way. Evidence of a right-of-way is visible in some locations, primarily at cross-streets and where the right-of-way has been converted to driveways or paths. General elements of rail lines are not visible.

Whittenton Right-of-Way and Bridge from King Philip Street, West of Route 138 (Nos. 42, 43)

These two viewpoints capture the location of the proposed Whittenton Branch of the Stoughton Line as it would cross over King Philip Street, west of Route 138 in Raynham, in both directions (Figure 4.5-17). The stone bridge abutments, built on either side of King Philip Street, are still present, but the actual bridge crossing the roadway is not present. King Philip Street is a narrow, two-lane suburban roadway without shoulders, flanked by single-family homes. The right-of-way embankment, visible from either side King Philip Street, is forested. This viewpoint was selected because grade crossing upgrades would be required as part of the Stoughton Alternative, Option 4C (now known as the Whittenton Alternative).

Whittenton Right-of-Way at Bay Street (Nos. 44, 45)

Two viewpoints of the Whittenton Branch right-of-way at Bay Street in Taunton were observed (Figure 4.5-18). Viewpoints of the right-of-way in both directions show that where the right-of-way intersects Bay Street, it ends in an embankment and the previous right-of-way under Bay Street has been filled. The right-of-way is heavily forested on either side of the roadway, although a cleared area hints at previous existence of a right-of-way. This viewpoint was selected because Bay Street would be replaced by a bridge.

Bay Street Bridge from Bay Street (No. 46)

A viewpoint facing southeast up Bay Street in Taunton shows the former Bay Street Bridge, a roadway passing over the Whittenton Branch right-of-way that was discussed above (Figure 4.5-18). This viewpoint was selected as the bridge would have to be reconstructed to accommodate a rail right-of-way. Located near downtown Taunton, Bay Street is a two-way roadway with shoulders, surrounded by a mix of uses, including detached residences south of the overpass and a restaurant and other commercial uses north of the overpass. The overpass has a guard rail and jersey barriers protecting a sidewalk from the embankment on the north side and no barrier or sidewalk on the south side.

Whittenton Right-of-Way and Grade Crossing from Warren Street (No. 49)

The right-of-way and grade crossing of the Whittenton Branch was observed from Warren Street in Taunton (Figure 4.5-19). Warren Street is a low-density residential neighborhood and the right-of-way is flanked by single-family homes. As this is an inactive right-of-way, there are currently no grade-crossing elements or tracks. However, the right-of-way is quite visible as a wide, gravel and dirt roadway. Automobile access is possible on the right-of-way, but restricted with swinging metal gates. West of Warren Street, jersey barriers also restrict access and the right-of-way is marked private property. This viewpoint was selected because there is currently no evidence of an operative right-of-way.

Stations

This section discusses the views and aesthetic resources of the proposed station sites, which are shown in Figures 4.5-20 through 4.5-29. All the viewpoints described below were selected because they are possible station sites.

Southern Triangle Station Sites—Common to All Rail Alternatives

The Southern Triangle includes two rail alignments south of Weir Junction. The six stations are common to all Build Alternatives. This section discusses the views and aesthetic resources of the proposed station sites for the Southern Triangle station sites.

Taunton Depot Station (No. 41)—The proposed Taunton Depot (formerly known as East Taunton [North]) Station site is behind the Target Plaza off of Route 140 in Taunton (Figure 4.5-20). The site is currently undeveloped, with half the site cleared and half the site forested. Six large floor-plan retail buildings, on the adjacent shopping plaza, contain numerous retail establishments and are generally in good condition. This proposed station site is not visible from Route 140 due to its location at the rear of an established shopping plaza and is not visible from other sides due to the forest cover.

King's Highway Station (No. 6)—The proposed King's Highway Station site is in a commercially developed area containing traditional strip retail development close to Route 140 in New Bedford (Figure 4.5-21). The site, in the rear of King's Highway Plaza, is highly visible from the intersection of King's Highway and Tarkiln Hill Road. King's Highway Plaza contains occupied buildings and a parking lot. The site contains one large floor-plate, strip-style retail building with approximately eleven establishments, one stand-alone fast-food restaurant building, and associated parking. The establishments are traditional single-story retail establishments in a variety of sizes and ages.

Whale's Tooth Station (No. 7)—The proposed Whale's Tooth Station site is adjacent to Route 18 and accessed from Acushnet Avenue in New Bedford (Figure 4.5-22). It is currently a parking lot, recently completed by the City of New Bedford in anticipation of the proposed project. The only structure on the site is a parking attendant booth. The station site is largely devoid of vegetation and can be viewed from Route 18, adjacent uses, and the higher elevation residences east of Route 18.

Freetown Station (No. 10)—The proposed Freetown Station site is off South Main Street in Freetown (Figure 4.5-23). The site is currently developed as a self-storage facility with associated parking; it is surrounded by open land and forest. The site contains four large storage buildings in fair condition. The station site can be viewed from South Main Street and the adjacent individual residences.

Fall River Depot Station (Nos. 11, 12)—The proposed Fall River Depot Station site is on Davol Street, which runs parallel to Route 138/Route 70 in Fall River (Figure 4.5-24). The station is currently developed as a commercial property with parking. Two buildings and steel framing for an apparent third building exist on the site; all are vacant. One building, a large metal building with five garage bays, was formerly used as a flooring supply warehouse and is in poor/fair condition. The second building, a brick structure, was used for office and storage uses and is in poor/fair condition. All the windows of the brick building have been filled in with concrete blocks or wood. The site is characterized by some vegetation due to inactivity at the site. This site is viewed from Davol Street, Pearce Street, and from the rear of properties across the tracks.

Battleship Cove Station (No. 13)—The proposed Battleship Cove Station site is on Water Street/Ponta Delgada Boulevard in Fall River (Figure 4.5-25). The site contains the Ponta Delgada Plaza, Gates of the City Monument, a circular driveway, and a grassed area. The station would be at the rear of the site, in a currently vegetated area that abuts Route 138/Broadway Extension to the southwest. The station site is visible from Route 138/Broadway Extension and from Eagle Street to the southeast, both of which are at a higher elevation. The site is also visible from the industrial uses along the waterfront and the high-density residential uses southwest of Route 138.

Stoughton and Whittenton Alternatives Station Sites

In addition to the Southern Triangle, the Stoughton Alternatives and the Whittenton Alternatives would provide commuter rail service from South Station through Stoughton to Canton Junction and Weir

Junction. This section discusses the views and aesthetics resources of proposed station sites for the Stoughton and Whittenton Alternatives outside of the Southern Triangle.

Stoughton Station—The relocated Stoughton Station would be a new train station constructed along the Stoughton Line, west of the existing railroad tracks and north of Brock Street. The site is a previously developed area consisting of commercial/industrial businesses, parking areas, and some undeveloped wooded land. It is adjacent to commercial/industrial businesses and residences along Morton Street, residences along Brock Street, and commercial businesses and parking lots on the east side of the railroad tracks. The site is visible from Brock Street immediately west of the grade crossing, and from the rear of the abutting businesses and residences.

North Easton Station Site (No. 23)—The proposed North Easton Station is off Route 138 in Easton, behind the Roche Brothers Shopping Plaza (Figure 4.5-26). The station site is undeveloped and entirely vegetated, but has evidence of earthwork, most likely as a result of the construction of the shopping plaza. In addition to the shopping plaza to the east, the site is adjacent to forested land to the west (where the rail right-of-way would pass) and south. The shopping plaza contains six buildings in excellent condition as all are relatively new. A medical office building adjacent to the proposed station site is the newest building.[5] This site is not visible from Route 138 due to its location at the rear of an established shopping plaza and is not visible from other sides due to the forest cover. The site is visible from the medical office building.

Easton Village Station (Site No. 24)—The proposed Easton Village Station site is off Sullivan Avenue just north of the Easton Town Center (Figure 4.5-27). The station site is adjacent to a historic train station, designed by Henry Hobson Richardson, and a small parking area. The historic train station is in good condition and is the home of the Easton Historical Society. Located in a dense town center, the site is visible only from the roads and parcels surrounding it, which include Shovel Shop Pond, the YMCA and a converted mill building as well as the historic station.

Raynham Park Station Site (No. 29)—The proposed Raynham Park Station site is at the site of the former Raynham-Taunton Greyhound Track, off Route 138 in Raynham (Figure 4.5-28). The station site itself is within a larger, developed site that currently includes a simulcast/off-track betting facility and a parking area. The station site is not visible from the main road because it is accessed via a driveway from the larger Raynham Park recreational site.

Dana Street Station Site—The proposed Dana Street Station site is located just south of the Danforth Street grade crossing, within walking distance of downtown Taunton. This station would only serve the Whittenton Alternatives. The station would be on the east side of the railroad, between the alignment and Dana Street. The approximately 3.53-acre site is a currently vacant lot that appears to have been occupied by an industrial use. The area surrounding the site is densely developed with land uses including commercial, industrial, and residential properties. The station site is visible from Danforth Road to the west due to the absence of vegetation along the site's perimeter. The residential developments west of Danforth Road do not have direct or unobstructed views into the site due to vegetation screening and the orientation of the residential development. The station site is partially visible from Dana Street to the north. The parcels north of Dana Street opposite the station site have a partial view into the site. However this area is vacant. No public views are available into the Dana Street station site from the south, as this area is occupied by an existing rail line. Public views into the Dana

[5] The building is not shown on the 2005 MassGIS orthophoto in Figure 4.5-26 since it was constructed after 2005.

Street from the east are not available as the parcel south of the station site is occupied by auto-related industrial land uses.

Taunton Station (Dean Street) Site (No. 38)—The proposed Taunton (Dean Street) Station site, which would only serve the Stoughton Alternatives, is off Arlington Street in Taunton (Figure 4.5-29). The site is a formerly developed parcel now containing vacant buildings and other derelict areas as a result of fire. The site is in a developed area, and is visible from the intersection of Dean and Arlington Streets (south), from the frontage at Arlington Street and the residences lining that street (west), and from the town playing fields on Longmeadow Avenue east of the site, across the rail right-of-way.

Layover Facilities

This section discusses the views and aesthetic resources of the two identified layover facility sites – the Wamsutta site along the New Bedford Main Line and Weaver's Cove East site along the Fall River Secondary. Layover facility plans are conceptual at this point, consisting only of general layouts and footprints. Tracks at the train layover facilities would diverge from the respective through lines (Fall River Secondary, or New Bedford Main Line) and consist of a series of short parallel spurs upon which trains would be parked for overnight layovers and light maintenance work. Parking areas for employees would be included within the facilities, and hooded lights would minimize light pollution. Small site structures are planned for storage and personnel change rooms. The facilities would be fenced and lighted for security. Engineering plans will be completed for these facilities once the LEDPA has been determined.

Wamsutta Layover Facility Site

The proposed Wamsutta layover facility would be constructed along the New Bedford Main Line and would serve all Build Alternatives. It would be located in New Bedford near the intersection of Wamsutta Street and Herman Melville Boulevard, near the southern terminus of the New Bedford Main Line, just north of the Whale's Tooth Station.

The Wamsutta site is a previously developed site, currently used as a rail yard for CSX, within an industrial area. The site is visible from adjacent roads and buildings. Adjoining properties are transportation corridors or industrial in nature. Industrial sites are located north, east, and south of this location, and Route 18 to the west. No commercial or residential properties, or open spaces, are located in close proximity to this site.

Weaver's Cove East Layover Facility Site

The proposed Weaver's Cove East layover facility would be constructed along the Fall River Secondary and would serve all Build Alternatives. It would be located in Fall River west of Main Street between the existing Fall River Secondary and Main Street, approximately 2.5 miles from the southern terminus of the Fall River Secondary.

Currently vacant land, a portion of the Weaver's Cove East site was previously developed. Approximately one-half of the site is cleared of vegetation or includes remnant building foundations; the remainder of the site is vegetated. Surrounding land to the north, east, and south is residential; industrial land use is present to the southwest. Undeveloped land is immediately west of the site, adjoining the Taunton River. The industrial site to the southwest is a former Shell Oil facility, and consists of completely cleared land with several large aboveground storage tanks and a short shipping

dock. The layover facility site is partially visible from the adjacent properties, somewhat obscured from view by vegetation. The layover facility would be visible from the Taunton River. As discussed below, this segment of the Taunton River has been designated as a "recreational river area," recognizing its aesthetic value and developed shoreline.

4.5.3 Analysis of Impacts

4.5.3.1 Introduction

For the purposes of this assessment, "visual and aesthetic resources" refers to the visible natural and built environment surrounding the various components of the alternatives, and this analysis examines changes in the physical appearance of that environment from a ground-level viewer's perspective. The following assessment identifies any changes in the visual setting that could have adverse impacts on the visual and scenic resources of importance to residents. The visual impacts are based upon examples or conceptual views of the major components of each of the alternatives as compared to the existing character of the surrounding environment. Visual impacts to historic resources are analyzed separately in Chapter 4.8, *Cultural Resources*.

4.5.3.2 Methodology

This section summarizes the methodology used to evaluate the potential direct and indirect effects of the South Coast Rail project to visual and aesthetic resources.

As required by the CEQ under NEPA,[6] the analysis of the environmental consequences includes discussion of the direct and indirect effects of a proposed action and their significance. Direct effects are defined as those "which are caused by the action and occur at the same time and place."[7] Indirect effects are defined as those "which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems."[8]

Similarly, MEPA requires "a detailed description and assessment of the negative and positive potential environmental impacts of the Project and its alternatives. The Environmental Impact Report (EIR) shall assess (in quantitative terms, to the maximum extent practicable) the direct and indirect potential environmental impacts from the Project that are within the Scope. The assessment shall include both short-term and long-term impacts for all phases of the Project (e.g., acquisition, development, and operation) and cumulative impacts of the Project, any other Projects, and other work or activity in the immediate surroundings and region."[9]

The following paragraphs describe how potential direct and indirect effects of the South Coast Rail alternatives to visual and aesthetic resources were evaluated.

[9] Massachusetts Environmental Policy Act Office. 2009. 301 CMR 11.00: *MEPA Regulations. Section 11.07: EIR Preparation and Filing, (6) Form and Content of EIR, (h) Assessment of Impacts.* Commonwealth of Massachusetts, Environmental Policy Act Office: Boston.

Direct Effects

Potential direct effects to visual and aesthetic resources were evaluated by examining preliminary engineering plans to identify new construction or significant reconstruction of existing facilities that may change the visual environment. Specifically, the following items were evaluated:

- Railroad improvements (upgrades to existing railroad track);
- Railroad construction (new track in active, abandoned, or previously unused railroad corridors);
- Railroad crossings (at-grade and grade separated crossings);
- Station reconstruction or construction (existing or new rail and/or bus stations);
- Layover facility construction (new spur tracks for overnight train storage); and
- For electric-powered alternatives, electrical infrastructure construction or upgrades (overhead catenary system and traction power facilities).

Preliminary engineering plans, conceptual views, and existing examples of similar facilities were reviewed and compared to current conditions to identify substantial changes in the visual environment. The existing visual environment is documented above in Section 4.5.2.

Visual impacts were qualitatively assessed based on a combination of the visibility of the specific component being evaluated and the context of the existing visual environment in which the component would be located.

The following ranking system was used:

- None: No visual impact would result because the evaluated component would not be visible to the general public and/or would not be different in character than the existing visual environment.
- Minimal: Visual impacts would be minor because the evaluated component would be only incidentally visible to the general public and/or would be a minor change from the existing visual environment.
- Moderate: Visual impacts would be modest because the evaluated component would be partially visible to the general public and/or would be a moderate change from the existing visual environment.
- Substantial: Visual impacts would be noteworthy because the evaluated component would be visible to the general public and/or would be a considerable change from the existing visual environment.

Changes in the visual and aesthetic environment may also affect the context in which cultural resources are viewed. This issue is specifically addressed in Chapter 4.8, *Cultural Resources*.

Indirect Effects

Indirect effects to visual and aesthetic resources may result from induced growth such as TOD in the vicinity of the train or bus stations. These indirect effects are addressed in a separate analysis described in Chapter 5, *Summary of Indirect Effects and Cumulative Impacts.*

4.5.3.3 Impacts of Alternatives by Element

No-Build (Enhanced Bus) Alternative

The No-Build Alternative would improve transit service to Boston from New Bedford, Fall River, and Taunton by adding more buses but using smaller capital investments than are proposed in the Build Alternatives. Under this alternative, no new rail or bus service would be provided to Southeastern Massachusetts.

The No-Build Alternative plan includes bus schedule enhancements, transportation demand management, and transportation policy enhancements for commuter bus. In addition to these enhancements, financial incentives would be offered by the Commonwealth to encourage the private commuter bus service operators to acquire a new fleet of fuel efficient and clean emission buses. The intent of these measures would be for these buses to provide rider comfort and amenities comparable to commuter rail service.

The existing highway alignments present a visually disturbed environment from natural conditions. The alignments would not change and no new highway construction would be required for the No-Build Alternative. Using these highways for this alternative would not affect any visual or aesthetic resources.

Park-and-Ride Lot Expansion/Bus Stations

Three existing Park-and-Ride facilities would be expanded or re-striped to improved capacity and traffic flow as part of the No-Build Alternative, as summarized below. The three affected Park-and-Ride facilities are:

- The West Bridgewater Park-and-Ride, located near the southwest corner of the intersection of Routes 106 and 24 in West Bridgewater;
- The Mount Pleasant Street Park-and-Ride, located on the northwest corner of the intersection of King’s Highway and Route 140 in New Bedford; and
- The Silver City Galleria Park-and-Ride, adjacent to the Silver City Galleria shopping mall in Taunton.

The Mt. Pleasant Street park-and-ride lot in New Bedford operates at approximately 80 percent of capacity. If future ridership projections for the area indicate a significant increase in ridership for this region, an expanded park-and-ride/bus station may have merit in the existing lot, on adjacent land, or at another suitable location in the general area.

A review of available information and parking occupancy studies indicates that a bus station/park-and-ride facility in the West Bridgewater area, near the existing Route 106/Route 24 park-and-ride lot, would be readily utilized. A bus station and park-and-ride could be combined into one potential intermodal station near the existing park-and-ride lot. The existing park-and-ride lot at Route 106 in West

Bridgewater operates at capacity, as does the existing park-and-ride lot at Route 104 in Bridgewater. These two lots also do not allow buses to enter or exit the lots to pick up or drop off commuters. Although plans are underway to provide 40 more spaces at the West Bridgewater park-and-ride, a new park-and-ride/bus station could provide full bus access /egress and larger park-and-ride facilities. This might capture additional riders for all three commuter bus services that travel by this location via Route 24.

As the existing Silver City Galleria Park-and-Ride is at capacity, existing paved parking lots nearby that appear vacant may be used for a potential new expanded park-and-rid/bus station, or other sites could be identified in the immediate area around the Silver City Galleria and the Route 24/Route 140 highway interchange. A new facility at or near the mall could easily integrate local fixed route GATRA bus service which already serves the mall throughout the day. This linkage to local fixed route bus service could also encourage ridership on commuter bus.

Additional signage may be installed at the park-and-ride/bus facilities to direct motorists to parking areas. The impacts to the visual environment from streetscape changes as a result of potential park-and-ride lots/bus station expansions would be an incremental addition to the existing conditions.

Southern Triangle

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all Build Alternatives. These rail lines form a rough triangular shape running south from Myricks Junction to Fall River (the Fall River Secondary) and from Weir Junction through Myricks Junction to New Bedford (the New Bedford Main Line), and are therefore referred to as the Southern Triangle (Figure 1.4-1). The following sections describe the environmental consequences to visual and aesthetic resources that may result from new construction for these two components of the South Coast Rail project. The northern part of the South Coast Rail study area is described in subsequent sections for each alternative.

Visual and Aesthetic Impacts along the Fall River Secondary Rail Segment

The 12.3 miles of existing freight track along the Fall River Secondary would be upgraded and maintained to Federal Rail Administration (FRA) Class 7 options[10] for the South Coast Rail project. The line would be double-track from Weir Junction to Myricks Junction, with a 0.9-mile third track for freight movements near Taunton Depot Station. A short segment of the line would be double-track south of Myricks Junction, 0.8 mile. The remainder of the line would be single-track, with the exception of 1.8-mile double-track section in Freetown and a 1.7-mile section in New Bedford. The public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. Grade crossings would be closed or consolidated whenever feasible. The existing freight service using the Fall River Secondary is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would need to be constructed along the length of the line, and two new traction power facilities would need to be constructed for the electric alternatives. Potential direct impacts to visual and aesthetic resources resulting from constructing the upgraded rail lines and electrical infrastructure are described below.

Two new stations would be constructed in Fall River (Battleship Cove and Fall River Depot) and one new station would be constructed in Freetown (Freetown). One new layover facility would be constructed in Fall River at the Weaver’s Cove East site. Potential direct impacts to visual and aesthetic resources

[10] FRA. 2009. 49 CFR 213.9 Classes of Track: Operating Speed Limits. US Department of Transportation, Federal Rail Administration.

resulting from constructing the new stations and layover facility along the Fall River Secondary are considered in the Stations and Layover sections, respectively.

Beginning at Myricks Junction, the Fall River Secondary (as shown in Figure 1.4-1) passes through low density residential development, undeveloped land, and open space in Berkley, Lakeville, and Freetown. Passengers' views from the trains would be principally of residences, forest (including the Freetown-Fall River State Forest), and occasional ponds or rivers through most of this segment. Some industrial and commercial developments would also be visible, and the railroad crosses or parallels major highways such as Routes 24 and 79. Approaching Fall River, the alignment runs along the east bank of the Taunton River, with expansive views to the west.

Segments of the Taunton River were recently designated[11] as "scenic" or "recreational" river areas under the Wild and Scenic Rivers Act,[12] the segment along this portion of the Fall River Secondary is designated as a "recreational river area," which is defined by the Act as a segment with a partially developed shoreline and ready access.[13] Within Fall River, land development intensifies, with dense residential development, industrial properties, and commercial districts adjacent to and visible from the railroad. Near the end of the line, the railroad passes historic sites such as the Fall River Heritage State Park, with views of the World War II battleship U.S.S. Massachusetts. The final stop of the passenger rail service would be the Battleship Cove Station, at the Ponta Delgada monument. This location commemorates the City of Fall River's sister city, Ponta Delgada, through a recreation of the City Gates of Ponta Delgada in Sao Miguel, Azores.

Components of the Fall River Secondary improvements that would potentially change the visual and aesthetic environment are:

- Railroad upgrades, including track, railroad bed, bridges, and culverts;
- At-grade crossing improvements, including modern lights, automatic gates, curbs, and painted signage for traffic control; and
- Electrical infrastructure construction (electric alternatives only), including overhead catenary system and traction power facilities.

Railroad upgrades are not expected to substantially affect the visual environment along the Fall River Secondary for passengers, occupants of adjoining properties, or passers-by. The functionally upgraded track, railroad bed, bridges, and culverts would appear similar to the existing visual environment. The railroad upgrades within this portion of the Fall River Secondary within 0.25 mile of the Taunton River will not degrade the existing visual character of the partially developed shoreline along this "recreational river area" and no railroad bridges cross the river in this segment. For safety considerations, the right-of-way would be fenced where it passes through dense residential or downtown areas, presenting a minor visual impact by the addition of a chain-link fence to these environments.

[11] *Omnibus Public Lands Management Act of 2009*.
[12] *Wild & Scenic Rivers Act.* (16 USC 1271-1287); Public Law 90-542. 1968.
[13] No segment of the Taunton River was designated as "wild" (free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and unpolluted) and no segments adjacent to the Fall River Secondary are designated as "scenic" (free of impoundments, with shorelines and watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads).

Improving or reconfiguring the at-grade crossings would affect the appearance of these areas. All existing grade crossings to remain and all reactivated crossings would be equipped with new, state-of-the-art Automatic Highway Crossing Warning (AHCW) systems. Each crossing would be supported by a minimum 8-foot by 8-foot aluminum shed that would house the AHCW system. The houses would be placed at the most advantageous quadrant of the crossing to not impede sight distance of pedestrians, motorists, and train engineers. Existing lights and gates would be replaced with new structures to improve safety; the new structures would be intentionally more visible than the existing lights and gates, for greater contrast with the existing visual environment. Ground level traffic controls (curbs and painted signage) are not expected to substantially alter the existing visual environment. The at-grade crossings would be visible principally to automobile drivers and passengers, as well as occupants of adjacent properties. The crossings would be only incidentally visible to train passengers. A photograph of a modern at-grade crossing on another railroad line is provided in Figure 4.5-30.

Constructing the electrical infrastructure necessary to support the electric alternatives would affect the visual environment along portions of the Fall River Secondary by introducing new metal structures and wires into a rural setting. The overhead catenary system would include catenary supports at regular intervals, and electrical wires along the length of the line. The overhead catenary system would be visible to occupants of adjacent properties and automobile drivers and passengers at crossing or paralleling locations. In segments where the visual environment is particularly sensitive, the catenary supports may be designed to a lower profile appearance to minimize effects on surrounding visual environment. Photographs of typical overhead catenary systems on another railroad are provided in Figure 4.5-31.

Two new traction power facilities, paralleling stations, would be constructed in Fall River to deliver electric power from the regional transmission lines to the overhead catenary system. Paralleling stations contain less equipment than the main substation and switching stations and require a 40-foot by 80-foot site. One paralleling station (PS-5) would be adjacent to the Fall River Depot Station, and would be visible to passengers, other users of the station, occupants of adjacent properties, and potentially to passers-by on Route 138. Figure 4.5-33 shows the proposed traction power system and Figure 4.5-32 provides photographs of existing similar-appearing traction power facilities along another railroad line. The second paralleling station (PS-4) would be located in Freetown. Although it would be visible to passengers, other users of the stations and potentially from adjacent uses, it would not be expected to substantially alter the visual environment.

Visual and Aesthetic Impacts along the New Bedford Main Line Rail Segment

The 19.4-mile existing freight tack along the New Bedford Main Line would be upgraded to FRA Class 7 options for the South Coast Rail project. The line would be double-track from Weir Junction to Myricks Junction, with a 0.9-mile third track for freight movements near Taunton Depot Station. A short segment of the line would be double-track south of Myricks Junction, 0.8 mile. The remainder of the line would be single-track, with the exception of 1.8-mile double-track section in Freetown and a 1.7-mile section in New Bedford. The existing public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. Grade crossings would be closed or consolidated whenever feasible. The existing freight service using the New Bedford Main Line is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would need to be constructed along the length of the line, and four traction power facilities would be constructed for the electric alternatives. Potential direct impacts to visual and aesthetic resources resulting from constructing the upgraded rail lines and electrical infrastructure are described below.

Two new train stations would be constructed in New Bedford (Whale's Tooth and King's Highway) and one new train station would be constructed in Taunton (Taunton Depot). One new layover facility would be constructed in New Bedford at the Wamsutta site. Potential direct impacts to visual and aesthetic resources resulting from the constructing and using the new stations and layover facilities along the New Bedford Main Line are considered in the sections on Stations and Layovers, respectively.

Beginning at Weir Junction, the New Bedford Main Line (as shown in Figure 1.4-1) crosses the Taunton River and passes through undeveloped land, open space, and low density residential development, in Taunton, Berkley, Lakeville, and Freetown. Passengers' views from the trains would be principally of forest (including the Assonet Cedar Swamp), occasional ponds or rivers (including a "recreational river area" segment of the Taunton River), and residences through most of this segment. Industrial development begins in southern Freetown and increases in density in New Bedford; the industrial sites would be visible, as would the Acushnet Cedar Swamp open space in northern New Bedford. The railroad crosses Route 140 as it enters the densely developed part of New Bedford; views from the train would include industrial and residential development in this segment. Historic downtown New Bedford, near the New Bedford Whaling National Historic Park, would be visible to passengers. After crossing Route 18, the final stop of the passenger rail service would be the Whale's Tooth Station in a commercial/industrial area.

Components of the New Bedford Main Line improvements that would potentially change the visual and aesthetic environment are:

- Railroad upgrades, including track, railroad bed, bridges, and culverts;
- At-grade crossing improvements, including modern lights, automatic gates, curbs, and painted signage for traffic control; and
- Electrical infrastructure construction (electric alternatives only), including overhead catenary system and traction power facilities.

Railroad upgrades are not expected to substantially affect the visual environment along the New Bedford Main Line for passengers, occupants of adjoining properties, or passers-by. The upgraded track, railroad bed, bridges (with one exception), and culverts would appear similar to the existing visual environment. For safety considerations, the right-of-way would be fenced where it passes through dense residential or downtown areas, presenting a minor visual impact by the addition of a chain-link fence to these environments.

As noted above, segments of the Taunton River were recently designated as "scenic" or "recreational" river areas. The New Bedford Main Line crosses the Taunton River in Taunton, immediately south of Weir Junction. This segment of the river is designated as a "recreational river area." The existing single track bridge at this location was constructed in 1906 and partially rebuilt in 1942.[14] It is approximately 130 feet long, consists of four spans of varying lengths, was constructed as a combination of open deck beams and thru-girders, and is supported by three sets of steel H-pile piers and concrete and stone masonry abutments. This bridge is in poor condition, and is structurally inadequate to support the proposed train loads (or number of tracks) required for the South Coast Rail project.

[14] Vanasse Hangen, Brustlin, Inc. (VHB) 1995. Undergrade Bridge Inspection and Rating Report, MBTA New Bedford/Fall River Commuter Rail Project. Vanasse Hangen Brustlin, Inc.: Boston.

The proposed replacement structure is envisioned to be a two-span, two-bay, ballasted steel plate thru girder superstructure carrying two sets of tracks. There would be three total girders, with two exterior and one common interior girder. New cast-in-place concrete abutments would be constructed behind the existing abutments, increasing the span length. The existing abutments would be partially removed to an elevation equal to the river's average seasonal high water elevation. The space between the existing and proposed abutments would be graded to reconnect the stream banks on either side of the bridge. The existing piles would be removed to one foot below grade. This design would enable riverbank and wildlife passage to be restored in front of the new abutments. The proposed bridge configuration would reduce the number of piers within the waterway, providing a cleaner, more consistent appearance, and the ballasted superstructure would help to suppress vibration noise during train crossings.

The proposed bridge would permanently alter the visual environment of the recreational river area, but the visual character of this partially developed shoreline would not be adversely affected. The bridge construction activities, potentially including cofferdams, would temporarily adversely impact the visual character of the river in this segment.

Improving or reconfiguring the at-grade crossings would affect the appearance of these areas. All existing grade crossings to remain and all reactivated crossings would be equipped with new, state-of-the-art AHCW systems. Each crossing would be supported by a minimum 8-foot by 8-foot aluminum shed that would house the AHCW system. The houses would be placed at the most advantageous quadrant of the crossing to not impede sight distance of pedestrians, motorists, and train engineers. Existing lights and gates would be replaced with new structures to improve safety; the new structures would be intentionally more visible than the existing lights and gates, for greater contrast with the existing visual environment. Ground level traffic controls (curbs and painted signage) are not expected to substantially alter the existing visual environment. A more visible change would be implemented at the Tarkiln Hill Road crossing in New Bedford. Tarkiln Hill Road would be closed on the west side of the tracks, and traffic routed to King's Highway, which intersects the current alignment of Tarkiln Hill Road at the crossing location (Figure 4.5-34). East of the crossing, the existing Tarkiln Hill Road alignment would remain, but with modern at-grade crossing improvements. The at-grade crossings would be visible principally to automobile drivers and passengers, as well as occupants of adjacent properties. The crossings would be incidentally visible to train passengers. A photograph of a modern at-grade crossing on another railroad line is provided in Figure 4.5-30.

Constructing the electrical infrastructure necessary to support the electric alternatives would affect the visual environment along portions of the New Bedford Main Line by introducing new metal structures and wires into a rural setting. The overhead catenary system would include catenary supports at regular intervals, and electrical wires along the length of the line. The overhead catenary system would be visible to occupants of adjacent properties and automobile drivers and passengers at crossing or paralleling locations. In segments where the visual environment is particularly sensitive, the catenary supports may be designed to a lower profile appearance to minimize impacts to surrounding visual environment. Photographs of typical overhead catenary systems on another railroad are provided in Figure 4.5-31.

Four new traction power facilities would be constructed along the New Bedford Main Line to deliver electric power from the regional transmission lines to the overhead catenary system. Figure 3-33 shows the proposed locations of the traction power facilities and Figure 3-32 provides photographs of existing similar traction power facilities along another railroad line. One traction power substation (TPSS-2)

would be located in New Bedford. Traction power substations (or main substations) draw power from the utility power grid. A typical main substation site is 150 feet by 200 feet. Two new paralleling stations, each which require a 40-foot by 80-foot site, would be constructed along the New Bedford Main Line; one each in New Bedford (PS-6) and Freetown (PS-3). Switching stations are required where two sections of the traction power system powered from different main substations meet; switching station sites can be as large as 60 feet by 150 feet. One switching station (SWS-2) would be located in Berkley where the Fall River Secondary joins the New Bedford Main Line. The paralleling and switching stations would be visible from nearby vantage points, but are not expected to substantially affect the visual environment. The traction power substation would adversely impact the visual environment from adjacent locations.

Stoughton Electric Alternative

The Stoughton Electric Alternative north of the Southern Triangle would be comprised of a portion of the Northeast Corridor and the entire Stoughton Line. This alternative would use 15.5 miles of the existing Northeast Corridor track infrastructure between from South Station to Canton Junction. From Canton Junction, the existing, active Stoughton Line would be used to Stoughton Station. Commuter rail service would be extended along the Stoughton Line using an out-of-service railroad bed, south through Raynham Junction to Weir Junction in Taunton, at which point this alignment joins the New Bedford Main Line.

The Stoughton Electric Alternative does not include any construction along the Northeast Corridor. The existing single track Stoughton Line would be upgraded to FRA Class 7 for the Stoughton Electric Alternative. A new second track would be constructed from Canton Junction to the existing Stoughton Station, a distance of 3.8 miles, where existing passenger service ends. A new double track would extend south of Stoughton Station to the proposed North Easton Station. The remainder of the line south to Weir Junction would be single- track, with a 2.2-mile long double-track section in Raynham, and a 0.6 mile long double-track section in Taunton. Approaching Weir Junction, an additional 0.4 mile siding track would be provided for freight use only. All of the existing at-grade road/railroad crossings would be reconfigured and/or improved to meet current safety standards. Grade crossings would be closed or consolidated whenever feasible. New catenary supports and wires would be constructed along the length of the line, and four new traction power facilities would be constructed. Potential direct impacts to visual and aesthetic resources resulting from constructing the upgraded rail lines and electrical infrastructure are described below.

This evaluation focuses on the existing and extended Stoughton Line segment from Canton Junction to Weir Junction. The shared Southern Triangle segment of the Build Alternatives was addressed in the preceding section, and no construction is proposed for the Northeast Corridor portion of the alignment.

One existing train station (Canton Center) along the active portion of the Stoughton Line would be reconstructed. Five new train stations (Stoughton, North Easton, Easton Village, Raynham Park, and Taunton) would be constructed. No new layover facilities would be constructed along this segment. Potential direct impacts to visual and aesthetic resources from reconstructing the existing and developing the new stations along the Stoughton Line are considered in the Stations section.

Beginning at Canton Junction, the active portion of the Stoughton Line passes through high density commercial, industrial, and residential development in Canton and Stoughton. The active portion of the Stoughton Line, beginning at just south of the Stoughton Station, passes through a mixture of moderate density commercial, industrial, and residential development. The visual environment from Canton

Junction to the southern portion of the town of Stoughton would be variable from the riders' perspective, including all of these components. The visual environment in the southern portion of Stoughton is marked by the Stoughton Memorial Conservation Land on the west side of the alignment. This area is predominantly forested open space but with interspersed low density residential and commercial development. Views to the east in this segment would be similar in character but dominated by the Route 138 highway and commercial development paralleling the railroad.

Entering Easton, the alignment passes through additional open space and is adjacent to low- to moderate-density rural development, with development density increasing in downtown Easton and adding commercial and industrial elements. In Easton Village, the railroad passes through or near the H. H. Richardson Historic District and the North Easton Historic District. The existing train station in Easton is a national historic landmark (the new Easton Village Station would be located immediately south of this site). The visual environment transitions back to low and moderate density development as the railroad alignment continues south. Views from the train would include forested open space, residential development, and recreational sites (golf courses) in this segment. The railroad enters the Hockomock Swamp ACEC and Wildlife Management Area in the southern portion of Easton, with only open space land use after crossing an electrical transmission line corridor. Views from the train in this segment would be exclusively of forested land until the alignment enters Raynham and passes the Raynham Park former greyhound dog racing track and some industrial development. Views from the train in this segment would include both open space and this recreational/industrial property. The Stoughton Line crosses I-495, passing through or near a commercial business district as it crosses Route 138. The visual environment then changes as it briefly passes through moderate density residential development before entering the Pine Swamp open space just north of Taunton. The visual environment in Taunton is a mixture of residential, commercial, and industrial development with some open space. Passengers on the Stoughton Line would view the Taunton River three times before the railroad joins the New Bedford Main Line at Weir Junction (described above). The Taunton River crossings are within a segment of the river designated as a "recreational river area" within the National Wild and Scenic Rivers System through the National Park Service.

Components of the Stoughton Line improvements and construction for the Stoughton Electric Alternative that would potentially change the visual and aesthetic environment are:

- Railroad upgrades and construction, including track, railroad bed, bridges, and culverts;
- Trestle construction, consisting of a low-rise bridge about the existing railroad bed;
- At-grade grade crossing improvements and construction, including modern lights, gates, curbs, and painted signage for traffic control;
- Grade-separated crossing construction, consisting of a road bridge over the railroad;
- Frontage road construction, consisting of a short segment of paved road along a portion of the line in Stoughton; and
- Electrical infrastructure construction, including overhead catenary system and traction power facilities.

Railroad upgrades would minimally affect the visual environment along the existing, active Stoughton Line for passengers, occupants of adjoining properties, or passers-by. The upgraded track, railroad bed,

bridges, and culverts would appear similar to the existing visual environment. For safety considerations, the right-of-way would be fenced where it passes through dense residential or downtown areas, presenting a minor visual impact by the addition of a chain-link fence to these environments.

Reconstructing the railroad along the out-of-service railroad bed from the Stoughton Station south to Weir Junction would substantially affect the visual environment in this segment for occupants of adjoining properties and passers-by. Although the historic railroad bed is present, the tracks were removed in some areas in the late 1950s and much of the alignment is currently used for informal recreation by pedestrians, bicyclists, and all-terrain vehicle (ATV) riders. The limits of disturbance for the new construction of this segment are generally less than 100 feet wide, for wetlands and upland areas, as illustrated in Figures 4.16-2a-2q. The disturbance would include clearing vegetation for the width of the right-of-way along the corridor for safety, visibility, and railroad bed maintenance. Limits of disturbance and vegetation clearing will be minimized to 40 feet wide through special design measures within certain wetland areas, such as the Hockomock Swamp, where a trestle will be constructed. The corridor passes through areas with a variety of land uses, ranging from commercial and industrial to residential and open space. The visual impact from clearing vegetation and reconstructing the railroad within commercial or industrial development, or along active transportation corridors (e.g., highways), would range from minimal to substantial for occupants of adjoining properties and passers-by. Where the alignment passes through or adjacent to residential or open space areas, the visual impact would be more substantially adverse to occupants of adjoining properties and recreationists by the addition of the railroad to a residential or recreational landscape.

As noted above, segments of the Taunton River were recently designated as “scenic” or “recreational” river areas under the National Wild and Scenic Rivers System through the National Park Service. The out-of-service Stoughton Line crosses the Taunton River three times and the tributary Mill River once, immediately north of Weir Junction. All four of these bridges have been recently retrofitted to accommodate a 24-inch diameter water main, attached to the south exterior side of the existing bridge superstructures. This segment of the Taunton River (and including the Mill River within a 0.25-mile wide corridor) is designated as a “recreational river area.” Listed from north to south, these bridges include:[15]

- The 118-foot long bridge across the Taunton River at milepost 34.38 (adjacent to Dean Street) was originally constructed in 1907 and rehabilitated at a later, unknown, date, and currently accommodates one track. The bridge is an open timber deck, steel trestle structure consisting of 11 spans of varying length and superstructure type. The bridge is in poor condition, and is not structurally adequate to support the proposed train loads required for the South Coast Rail project.

- The proposed structure is envisioned to be a two-span, ballasted steel thru girder superstructure carrying a single track. The existing piles would be removed to two feet below grade and a new, pile supported, cast-in-place concrete pier would be constructed in the center of the span. New cast-in-place concrete abutments would be constructed behind the existing timber crib abutments, increasing the span length of the bridge. The existing abutments would then be partially removed to an elevation equal to the river’s average seasonal high water elevation. The space between the existing and proposed abutments would be regraded to recreate the river banks on either side of the bridge.

[15] VHB. 1995. Undergrade Bridge Inspection and Rating Report, MBTA New Bedford/Fall River Commuter Rail Extension Project, Stoughton Line. Vanasse Hangen Brustlin, Inc.: Boston.

- The 171-foot long bridge across the Taunton River at milepost 34.62 was also constructed in 1907 and rehabilitated at a later, unknown date, and currently accommodates one track. This bridge is an open timber deck, steel trestle structure consisting of 15 spans of varying length and superstructure type. The existing bridge is in poor condition, and is not structurally adequate to support the proposed train loads required for the South Coast Rail project.

- The proposed structure is envisioned to be a two-span, ballasted steel thru girder superstructure carrying a single track. The pile would be removed to two feet below grade and a cast-in-place concrete pier would be constructed in the center of the span. New cast-in-place concrete abutments would be constructed behind the existing timber crib abutments, increasing the span length. The existing abutments would be partially removed to an elevation equal to the river's average seasonal high water elevation. The space between the existing and proposed abutments would be graded to recreate the stream banks on either side of the bridge.

- The 176-foot long bridge across the Taunton River at milepost 34.73 was constructed at an unknown date but likely in the same timeframe as the two listed above, and currently accommodates one track. The bridge is an open timber deck, steel trestle structure consisting of 17 spans of varying length. The bridge is in poor condition, and is not structurally adequate to support the proposed train loads required for the South Coast Rail project.

- The proposed structure is envisioned to be a two-span, ballasted steel thru girder superstructure carrying a single track. The piles would be removed to two feet below grade and a cast-in-place concrete pier would be constructed in the center of the span. New cast-in-place concrete abutments would be constructed behind the existing timber crib abutments, increasing the span length. The existing abutments would be partially removed to an elevation equal to the river's average seasonal high water elevation. The space between the existing and proposed abutments would be graded to recreate the stream banks on either side of the bridge.

- The 36-foot long bridge across the Mill River at milepost 34.90 was constructed at an unknown date but likely in the same timeframe as the two listed above, and currently accommodates one track. This bridge is an open timber deck structure consisting of a single span and is supported by two steel plate girders. The bridge is in poor condition, and is not structurally adequate to support the proposed train loads required for the South Coast Rail project.

- The proposed structure is envisioned to be a single-span, ballasted steel tub superstructure carrying a single track. New cast-in-place concrete abutments would be constructed behind the existing abutments, increasing the span length. The existing abutments would be partially removed to an elevation equal to the river's average seasonal high water elevation. The space between the existing and proposed abutments would be graded to reconnect the stream banks on either side of the bridge.

The existing 24-inch water main would be temporarily relocated off the existing bridges, to facilitate their demolition and the construction of the proposed replacement bridges. It is envisioned that the

water main would be supported during construction operations by means of temporary utility bridges, located within close proximity to the railroad bridges. In conjunction with the installation of ballast and rail, the existing water main would be relocated onto the new bridge superstructures. At this time, the temporary utility bridges would be permanently removed.

The proposed replacement bridges are configured to enable riverbank reconstruction and wildlife passage in front of the new abutments. In addition, these bridge configurations would reduce the number of piers within the waterway, providing a cleaner, more consistent appearance and better accommodating boaters, and the ballasted superstructures would help to suppress vibration noise during train crossings.

The visual environment of the recreational river area would be permanently altered by the new bridges, but the visual character of this partially developed shoreline would not be adversely affected. The bridge construction activities, potentially including cofferdams, would temporarily adversely impact the visual character of the river in this segment.

A trestle would be constructed for the portion of the railroad passing through the Hockomock Swamp area to allow for wildlife passage and to maintain the current hydrologic regime. The trestle (including catenary structures similar to the rest of the railroad) would be distant from any homes, businesses, or roadways and therefore not visible from those locations. Vegetation clearing along this portion would be limited to a 40-foot width to accommodate safe passage of the trains. A conceptual view of the trestle is provided in Figure 4.5-35. Photographs of typical overhead catenary systems on another railroad are provided in Figure 4.5-31.

Improving, reconfiguring, or constructing the at-grade crossings would moderately affect the appearance at these locations. All existing grade crossings to remain and all reactivated crossings would be equipped with new, state-of-the-art Automatic Highway Crossing Warning (AHCW) systems. Each crossing would be supported by a minimum 8-foot by 8-foot aluminum shed that would house the AHCW system. The houses would be placed at the most advantageous quadrant of the crossing to not impede sight distance of pedestrians, motorists, and train engineers. Existing lights and gates within the active Stoughton Line segment would be replaced with new structures to improve safety; the new structures would be intentionally more visible than the existing lights and gates, for greater contrast with the existing visual environment. Ground level traffic controls (curbs and painted signage) are not expected to substantially alter the existing visual environment. The at-grade crossings would be visible principally to automobile drivers and passengers, as well as occupants of adjacent properties. The crossings would be incidentally visible to train passengers. A photograph of a modern at-grade crossing along another railroad line is provided in Figure 4.5-30.

Within the inactive segment of the Stoughton Line, constructing modern railroad crossings where old crossings have been removed (or were never present) would affect the visual environment at these locations through the addition of metal structures and lights in new locations. Lights, gates, curbs, and/or painted pavement signage would be installed at each crossing. As with the railroad construction itself, the visual impact within commercial or industrial development, or along active transportation corridors (e.g., highways), would be minimal. Where the alignment passes through residential or open space areas (such as near Pine Swamp), the visual impact from adding the at-grade crossings would be moderate, through the introduction of metal structures and lights in a suburban or rural environment. The crossings would be visible to automobile traffic as well as adjacent residents and recreationists, but would be obscured from view from non-adjacent locations.

Constructing the grade-separated crossing at Broadway (Route 138) in Raynham (at mile post 31.31) would substantially affect the appearance of this area. Current plans call for a road bridge crossing above the railroad, depressing the track profile as required to provide adequate vertical clearance under the bridge. The road approaching the overpass from either side would be raised at a shallow angle to allow for appropriate visibility. The visual environment in the vicinity of the crossing, extending into the commercial zones along Broadway in either direction, would be impacted. The grade-separated crossing would be visible principally to automobile drivers and passengers, as well as occupants of adjacent properties. The crossing would be only incidentally visible to train passengers. A photograph of a grade-separated crossing along another railroad line is provided in Figure 4.5-36. Figure 4.5-37 shows the existing conditions at and the location of the proposed Route 138 grade-separated crossing.

Constructing the electrical infrastructure necessary to support the Stoughton Electric Alternative would moderately affect the visual environment along the Stoughton Line. The overhead catenary system would include catenary supports at regular intervals, and electrical wires along the length of the line. The visual impact is anticipated to be minimal within the active segment of the line and within the portions of the inactive segment that pass through commercially developed areas. The visual impact would be more substantial where the currently inactive segment passes through residential or open space areas. The electrical infrastructure would be visible to adjacent residents and recreationists, but would be obscured from view from non-adjacent locations. The electrical infrastructure would be particularly visible to residents of homes adjacent to the railroad, such as near downtown Easton. In segments where the visual environment is particularly sensitive, the catenary supports may be designed to a lower profile appearance to minimize impacts to surrounding visual environment. Photographs of typical overhead catenary systems along another railroad are provided in Figure 4.5-31.

Four new traction power facilities would be constructed to deliver electric power from the regional transmission lines to the overhead catenary system. These include a traction power substation (TPSS-1) and a paralleling station (PS-1) in Easton, a switching station in Canton (SWS-1), and a paralleling station (PS-2) in Taunton. Traction power substation sites are generally 150 feet by 200 feet, switching station sites can be up to 60 feet by 150 feet, and a typical paralleling station site is 40 feet by 80 feet. The traction power facilitates would impact the visual environment from adjacent locations. Most proposed sites for these facilities are generally removed from view by passers-by, therefore they have a visual impact on the surrounding environment, but are not frequently seen. They would be seen by passengers on the trains. Figure 4.5-33 shows the proposed locations of the traction power facilities and Figure 4.5-32 provides photographs of existing similar facilities along another railroad line.

However, paralleling stations 1, 2, and 5 do visually impact the surrounding environment. PS-5 is visible from Durfee Street to the east and Davol Street to the west in a commercial area, as illustrated in Figure 4.6-4c. PS-2 is located in a commercial area with residential populations, as illustrated in Figure 4.6-6g, which will negatively impact the adjacent properties to the west. PS-1 is located in an industrial area and will impact the visual environment of adjacent properties to the east, as illustrated in Figure 4.6-6i.

A frontage road would be constructed along the west side of the Stoughton Line between Morton Street and Totman Farm Road in Stoughton. The 30-foot-wide, 3,500-foot-long road would be paved, with a 6-foot wide sidewalk on the west side. An existing railroad bridge over Totman Farm Road would be reconstructed. The proposed structure is envisioned to be a ballasted steel tub superstructure carrying two sets of tracks. New cast-in-place concrete abutments are likely to be required, due to the current condition of the existing abutments. This portion of the Stoughton Line corridor is currently heavily vegetated; removing the vegetation for the frontage road in addition to the railroad construction

described above would further impact the visual environment in this area by removing the screening provided by the vegetation between the homes west of the railroad and Route 138. The east side of the railroad in this segment parallels Washington Street (Route 138); the west side adjoins low- and medium-density residential development. The frontage road would be visible to residents of adjacent homes and passengers on the train. The visual environment from the eastern perspective (Route 138) would be minimally impacted by the frontage road; the visual environment from the western perspective (homes) would be substantially impacted.

Stoughton Diesel Alternative

The Stoughton Diesel Alternative is identical to the Stoughton Electric Alternative with the exception of the locomotive power source. Diesel-powered train service differs from electric-powered service in not requiring electrical infrastructure, and therefore presents less of a visual impact. There would be no overhead catenary system or traction power facilities for the Stoughton Diesel Alternative. All other aspects of the Stoughton Diesel Alternative relevant to visual and aesthetic resources are the same as for the Stoughton Electric Alternative described above. Within the active segment, visual impacts would be limited to the grade crossing improvements. Within the out-of-service segment, visual impacts would be limited to vegetation clearing, the new at-grade crossings, and the replaced bridges over the Taunton and Mill Rivers.

Overall, the impacts to the visual environment from the Stoughton Diesel Alternative would be less than from the Stoughton Electric Alternative, due to the omission of electrical infrastructure along the Stoughton Line.

Whittenton Electric Alternative

The Whittenton Electric Alternative is identical to the Stoughton Electric Alternative alignment described above except for the segment of the Stoughton Line between Raynham Junction and Weir Junction. Specifically, at Raynham Junction the Whittenton Alternative would divert to the southwest to connect to the abandoned Whittenton Branch. The Whittenton Branch would extend south and west to the Attleboro Secondary at Whittenton Junction. Along the Attleboro Secondary, the Whittenton Alternative would extend to Weir Junction in Taunton. Track infrastructure improvements would include 3.6 miles of new single-track on the Whittenton Branch and 2.2 miles of single-track reconstruction on the Attleboro Secondary with a 0.3-mile siding reserved for the proposed Dana Street Station. The southernmost portion of the Stoughton Line, from Raynham Junction to Weir Junction (a distance of 5.1 miles), would be not be used if this alternative is selected. This evaluation focuses on the Whittenton Branch and Attleboro Secondary components; other components of this alternative are described in the preceding Southern Triangle and Stoughton Electric Alternative sections.

Visual and Aesthetic Impacts along the Whittenton Branch Rail Segment

New track would be placed on the out-of-service Whittenton Branch railroad bed from Raynham Junction to Whittenton Junction. The existing public at-grade road/railroad crossings would be reconfigured and/or improved to current safety standards. New catenary supports and wires would be constructed along the length of the line. No traction power facilities, stations or layover facilities would be constructed along this segment. Potential direct impacts to visual and aesthetic resources resulting from constructing the upgraded rail lines and electrical infrastructure are described below.

Beginning at Raynham Junction, the Whittenton Branch is adjacent to or passes through open space, moderate density residential development, and industrial properties in Raynham and Taunton. The

visual environment throughout this alignment would be variable from the riders' perspective, including all of these components. Notable sights include Prospect Hill Pond (east of the Whittenton Branch) and the Mill River crossing, both in Taunton. Passengers would view undeveloped forest land just prior to where the Whittenton Branch joins the Attleboro Secondary at Whittenton Junction.

Components of the Whittenton Branch improvements and construction for the Whittenton Electric Alternative that would potentially change the visual and aesthetic environment are:

- Railroad construction or reconstruction, including track, railroad bed, bridges, and culverts;
- At-grade crossing improvements and construction, including modern lights, gates, curbs, and painted signage for traffic control; and
- Electrical infrastructure construction, including overhead catenary system and traction power facilities.

Constructing the new railroad to replace the abandoned railroad tracks along the Whittenton Branch would minimally to moderately affect the visual environment in this segment for occupants of adjoining properties and passers-by. Vegetation has overgrown the existing railroad to some extent, although unauthorized all-terrain vehicle use has kept the alignment open. The new construction would require clearing vegetation for the width of the right-of-way (between 60 and 100 feet) in upland areas along the corridor for safety, visibility, and railroad bed maintenance. Vegetation clearing will be minimized within wetland areas, to between 40 and 60 feet wide.

The corridor passes through areas with a variety of land uses, ranging from commercial and industrial to residential and undeveloped land. The reconstructed railroad would be visible to occupants of adjacent properties and passers-by. Replacing bridges, such as at King Philip Street and Bay Street, would change the views along the crossed streets. The Mill River bridge is distinct from the crossing described in the section on the Stoughton Electric Alternative and is more than 0.25-mile from the "recreational river area" of the Taunton River. The bridge replacement here would change the visual environment of the Mill River, but because it is outside of the regulated buffer zone it is not evaluated in the context of the Wild and Scenic River designation of the Taunton River.

The visual impact from clearing vegetation and reconstructing the railroad within commercial or industrial development, or along active transportation corridors such as highways, would be minimal. Where the alignment passes through residential or undeveloped areas, the railroad would be visible and the visual impact would be more substantial by the introduction of rail service through a residential environment. Additionally, for safety considerations, the right-of-way would be fenced where it passes through dense residential or downtown areas, presenting a minor visual impact by the addition of a chain-link fence to these environments. The combination of additional fencing and active rail may dissuade the dumping of yard waste and other debris that presently occurs along the abandoned tracks, providing a potential improvement to the overall visual character of the corridor.

Along the inactive Whittenton Branch, constructing modern railroad crossings where old crossings have been removed (or were never present) would moderately affect the visual environment at these locations. Lights, gates, curbs, and/or painted pavement signage would be installed at each crossing. All crossings would be equipped with new, state-of-the-art Automatic Highway Crossing Warning (AHCW) systems. Each crossing would be supported by a minimum 8-foot by 8-foot aluminum shed that would house the AHCW system. The houses would be placed at the most advantageous quadrant of the

crossing to not impede sight distance of pedestrians, motorists, and train engineers. As with the railroad construction itself, the visual impact within commercial development (at Whittenton Street) would be minimal. Where the alignment passes through residential or open space areas (Warren Street), the visual impact from the at-grade crossing will be more substantial. The crossings would be visible to motorists as well as adjacent residents and recreationists, but would be obscured from view from non-adjacent locations. A photograph of a modern at-grade crossing along another railroad line is provided in Figure 4.5-30.

Constructing the electrical infrastructure necessary to support the Whittenton Electric Alternative would moderately affect the visual environment along the Whittenton Branch by introducing metal structures and wires into a residential environment. The overhead catenary system would include catenary supports at regular intervals, and electrical wires along the length of the line. The visual impact is anticipated to be minimal within the active segment of the line and within the portions of the inactive segment that pass through developed areas. The visual impact would be more substantial where the currently inactive segment passes through residential or undeveloped areas. The electrical infrastructure would be visible to adjacent residents and recreationists, but would be obscured from view from non-adjacent locations. Photographs of typical overhead catenary systems along another railroad are provided in Figure 3-31.

Visual and Aesthetic Impacts along the Attleboro Secondary Rail Segment

The Whittenton Electric Alternative includes 2.2 miles of single track reconstruction on the existing Attleboro Secondary with a 0.3-mile siding reserved for the proposed Dana Street Station. All of the existing at-grade road/railroad crossings would be reconfigured and/or improved to meet current safety standards. Grade crossings would be closed or consolidated whenever feasible. The freight service using the Attleboro Secondary is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would be constructed along the 2.2-mile length of the line shared by commuter trains. Potential direct impacts to visual and aesthetic resources resulting from constructing the upgraded rail lines and electrical infrastructure are described below.

One new train station would be constructed along this alignment in Taunton (Dana Street Station). No new layover facilities would be constructed along this segment. Potential direct impacts to visual and aesthetic resources from constructing and using the new station along the Attleboro Secondary are considered in the Stations section.

The relatively short, 2.2-mile Attleboro Secondary segment traverses downtown Taunton. Passengers would see the densely developed downtown area prior to reaching Weir Junction, where the Attleboro Secondary joins the New Bedford Main Line (described above).

Components of the Attleboro Secondary improvements for the Whittenton Electric Alternative that would potentially change the visual and aesthetic environment are:

- Railroad upgrades, including track, railroad bed, bridges, and culverts;
- At-grade crossing construction, including lights, gates, curbs, and painted signage for traffic control; and
- Electrical infrastructure construction, including overhead catenary system and traction power facilities.

Railroad upgrades minimally affect the visual environment along the Attleboro Secondary for passengers, occupants of adjoining properties, or passers-by. The upgraded track, railroad bed, bridges, and culverts would appear similar to the existing visual environment. For safety considerations, the right-of-way would be fenced where it passes through dense residential or downtown areas, presenting a minor visual impact by the addition of a chain-link fence to these environments.

Improving or reconfiguring the at-grade crossings would moderately affect the appearance of these areas. All existing grade crossings to remain and all reactivated crossings would be equipped with new, state-of-the-art Automatic Highway Crossing Warning (AHCW) systems. Each crossing would be supported by a minimum 8-foot by 8-foot aluminum shed that would house the AHCW system. The houses would be placed at the most advantageous quadrant of the crossing to not impede sight distance of pedestrians, motorists, and train engineers. Existing lights and gates would be replaced with new structures to improve safety; the new structures would be intentionally more visible than the existing lights and gates, for greater contrast with the existing visual environment. Ground level traffic controls (curbs and painted signage) are not expected to substantially alter the existing visual environment. The at-grade crossings would be visible principally to automobile drivers and passengers, as well as occupants of adjacent properties. The crossings would be only incidentally visible to train passengers. A photograph of a modern at-grade crossing on another railroad line is provided in Figure 4.5-30.

Constructing the electrical infrastructure necessary to support the Whittenton Alternative would also moderately affect the visual environment along the Attleboro Secondary by adding metal structures and wires to the existing railroad in a rural landscape. The overhead catenary system would include catenary supports at regular intervals, and electrical wires along the length of the line. The overhead catenary system would be visible to occupants of adjacent properties and motorists at crossing or paralleling locations. The electrical infrastructure would also be visible to residents of homes adjacent to the railroad, particularly near downtown Taunton. In segments where the visual environment is particularly sensitive, the catenary supports may be designed to a lower-profile appearance to minimize impacts to surrounding visual environment. Photographs of typical overhead catenary systems along another railroad are provided in Figure 3-31.

Figure 4.5-38 shows the proposed locations of the traction power facilities and Figure 4.5-32 provides photographs of existing similar facilities along another railroad line. One traction power facility, a paralleling station, would be constructed along the Attleboro Secondary for the Whittenton Electric Alternative. Paralleling stations typically require a 40-foot by 80-foot site. The paralleling station (PS-2) would be visible to train passengers, other users of the station, and occupants of adjacent commercial buildings, but would not substantially impact the visual environment of this developed area.

Whittenton Diesel Alternative

The Whittenton Diesel Alternative is identical to the Whittenton Electric Alternative with the exception of the locomotive power source. As described above for the Stoughton Diesel Alternative, diesel-powered train service differs from electric-powered service in not requiring electrical infrastructure, and therefore presents less of a visual impact. All other aspects of the Whittenton Diesel Alternative are the same as for the Whittenton Electric Alternative. Visual impacts would be limited to vegetation clearing and the grade crossing improvements.

Overall, the impacts to the visual environment from the Whittenton Diesel Alternative would be less than from the Whittenton Electric Alternative, due to the omission of electrical infrastructure along the Whittenton Branch.

Stations

This section provides basic descriptions of each train station, an indication of its appearance in reference to the existing visual environment, and a discussion about the visual impacts potentially resulting from constructing or reconstructing these stations for the South Coast Rail project.

Typically, the rail stations would consist of an 800-foot long platform to allow passengers to enter and exit the trains, a canopy on the platform, and parking lot. Some stations would not have dedicated parking lots (instead, they would share parking with other nearby facilities) and others would have parking structures rather than lots. Signage and safety lighting at the stations would be unobtrusive, but visible to passers-by and to some extent to occupants of adjacent properties. Variable message signs would be used, and downward-facing light hoods would be installed to minimize light pollution from safety lights. Typical details of side platform and center platform style stations are provided in Figures 4.5-39 and 4.5-40, respectively, for reference.

Battleship Cove Station

The Battleship Cove Station would use an existing developed area as a new train station that would serve all Build Alternatives. It would be located on Water Street in Fall River, near the southern terminus of the Fall River Secondary.

The Battleship Cove Station site was previously developed by the City for the Ponta Delgada Plaza. The station would be in a sparsely vegetated area at the rear of the plaza. The station would be visible from nearby higher elevation streets and similar-elevation industrial buildings and high-density residential areas.

A conceptual layout of this station is shown in Figure 4.5-41. The Battleship Cove Station would be a one side platform style (Figure 4.5-39). No parking lot is planned for this facility. The station would minimally affect the visual environment by replacing the existing vegetated area at the plaza with a new canopy and platform. The station would be visible to users, passers-by, and occupants of nearby buildings. Its appearance would be in keeping with the surrounding developed visual environment and monument. MassHighways has roadway improvement plans for Broadway south of the Battleship Cove Station, which include the construction of an on-/off-ramp from Broadway to Water Street, passing directly above the proposed track, just west of the rail platform. The MassDOT improvements would be visible from Battleship Cove station and impact the visual environment of station users.

Canton Center Station

The Canton Center Station is an existing train station along the Stoughton Line that would serve all Build Alternatives. It is located at 710 Washington Street in Canton. This station would be modified to accommodate a second track. A conceptual layout of the station is provided in Figure 4.5-42. Two new 800-foot long low-level platforms with mini-high platforms would be constructed (one adjacent to each track). Modifications to the tracks and platforms would require minor changes to the parking layout in the existing lots near the station, and no adjustments to the amount of existing parking spaces would be expected. Minor impacts to the visual environment would result from reconstructing the Canton Center Station.

Dana Street Station (Whittenton Alternatives)

The Dana Street Station would be a new station along the Attleboro Secondary that would serve only the Whittenton Alternatives. The station would be located west of Dana Street, just south of the Danforth Street grade crossing and within walking distance of downtown Taunton. The site is a previously developed, currently vacant parcel surrounded by dense development including commercial, industrial, and residential uses. It is visible from Danforth Road to the west. The residential developments west of Danforth Road do not have direct or unobstructed views into the site due to vegetation screening and the orientation of the residential development. The station site is partially visible from Dana Street to the north. However this area is vacant. No public views would be available into the Dana Street station from the south, as this area is occupied by an existing rail line. Public views into the Dana Street from the east are not available as the parcel south of the station site is occupied by auto-related industrial land uses.

A conceptual layout of the station is provided in Figure 4.5-43. This station would be a one side platform style (Figure 4.5-39). The visual environment would be affected by replacing the existing vacant lot with a new parking lot, sidewalk, canopy and platform. The station would be visible to users and passers-by. Its appearance would be in keeping with the existing developed visual environment. Impacts to the visual environment in the vicinity of the Dana Street Station would be minimal.

Easton Village Station

The Easton Village Station would be a new train station constructed along the Stoughton Line that would serve all Build Alternatives. The Easton Village Station site is on Sullivan Avenue at the transition point to Mechanic Street (near the intersection with Pond Street) in Easton.

The Easton Village Station site is a partially developed parcel surrounded by industrial and residential development. The site is in developed downtown Easton, adjacent to a historic train station and small parking area. The site is visible only from adjacent roads and properties.

A conceptual layout of this station is shown in Figure 4.5-44. The Easton Village Station would be a side platform style (Figure 4.5-39). The station would be a new structure consisting of a canopy, pedestrian ramp, and high-level platform on the west side of the tracks. A passenger drop-off location would be provided at the historic train depot parking lot east of the tracks, with pedestrian access to the station via an existing underpass at Pond Street. Standard parking facilities would not be included at this station. The station would be visible to users, passers-by, and occupants of nearby buildings.

As described above, the Stoughton Line right-of-way would be fenced where it passes through dense residential or downtown areas, presenting a visual impact by the addition of a chain-link fence to these environments. For the Easton Village Station, the fencing would be proximate to the historic district and historic train depot, altering the visual character of this area.

Adverse impacts to the visual environment in the vicinity of the new Easton Village Station would be substantial.

Fall River Depot Station

The Fall River Depot Station would be a new train station constructed along the Fall River Secondary to serve all Build Alternatives. It would be located near the intersection of North Davol Street and Pearce Street in Fall River.

The Fall River Depot Station site is a previously developed site surrounded by commercial and industrial development. Numerous commercial/industrial buildings in poor to fair visual condition are present on-site. The existing parking lots are also in poor condition. This site is visible from adjacent roads and nearby properties.

A conceptual layout of this station is shown in Figure 4.5-45. The Fall River Depot Station would be a side platform style (Figure 4.5-39). The station would favorably affect the visual environment by replacing the existing vacant commercial buildings and parking lot with a new canopy, platform, and parking deck. The station would be visible to users, passers-by, and occupants of nearby buildings. Its appearance would be an improvement compared to the existing vacant buildings and parking lots. Impacts to the visual environment in the vicinity of the Fall River Depot Station would be moderately beneficial.

Freetown Station

The Freetown Station would be a new train station constructed along the Fall River Secondary to serve all Build Alternatives. It would be located along South Main Street in Freetown. The Freetown Station site is behind a self-storage facility with associated parking; immediately adjacent properties are open land and forest. A cellular phone tower site is also adjacent. Low-density residential development is nearby. The self-storage facility contains four buildings in fair visual condition, and can be viewed from adjacent roads and residences. The self-storage facility and cell tower would remain at the site.

A conceptual layout of this station is included as Figure 4.5-46. The Freetown Station would be a side platform style (Figure 4.5-39). The station would affect the visual environment by adding a new access road, canopy, platform, and parking lot north and east of the existing self-storage facility. A bus drop-off loop would be included at this location. The station would be partially visible to users, passers-by, and occupants of nearby buildings, although off-site views would be obstructed by the existing buildings and surrounding vegetation. Impacts to the visual environment in the vicinity of the Freetown Station would be minimal.

King's Highway Station

The King's Highway Station would be a new train station constructed along the New Bedford Main Line to serve all Build Alternatives. It would be located near the intersection of King's Highway and Tarkiln Hill Road in New Bedford.

The King's Highway Station site is along the railroad right-of-way behind the King's Highway Plaza, a traditional strip mall (commercial development). The site is visible from adjacent roads and some of the commercial buildings. The existing retail establishments are in a variety of sizes and visual conditions.

Figure 4.5-47 shows the conceptual layout of this station. The King's Highway Station would be a side platform style (Figure 4.5-39). The station would affect the visual environment by adding a new canopy and platform. Parking would be shared with the existing, surrounding commercial businesses. The station would be partially visible to users, passers-by, and occupants of adjacent buildings. Its

appearance would be in keeping with the nearby developed visual environment. Impacts to the visual environment in the vicinity of the King's Highway Station would be minimal.

North Easton Station

The North Easton Station would be a new train station constructed along the Stoughton Line that would serve all Build Alternatives. It would be located at 21 Washington Street in Stoughton.

The North Easton Station site is an undeveloped parcel surrounded by commercial development and undeveloped land. The site is behind (west of) the Roche Brothers Shopping Plaza, with forested land and medical buildings also adjacent. The shopping plaza buildings and medical building are all in excellent visual condition. The site is not visible from adjacent roads or the shopping plaza, but is visible from the medical buildings. The perspective from the medical buildings would be from above, as the station would be at a much lower elevation.

A conceptual layout of this station is shown in Figure 4.5-48. The North Easton Station would be a center platform style (Figure 4.5-40). The center platform would be accessed by a passenger crossover (pedestrian bridge and stairs), approximately 23 feet tall. The station would affect the visual environment by replacing the existing vacant lot with a new canopy, platform, and parking lot. The station would be visible to users and occupants of the adjacent medical building, but not to passers-by on Route 138. Impacts to the visual environment in the vicinity of the North Easton Station would be minimal.

Raynham Park Station

The Raynham Park Station would be a new train station constructed along the Stoughton Line that would serve all Build Alternatives. It would be located at 1958 Broadway in Raynham, adjacent to the Raynham-Taunton Greyhound Park off of Route 138, which is currently operated as a simulcast betting location.

The Raynham Park site is a developed parcel that is a portion of surrounding recreational and industrial development; access to adjacent industrial facilities would be incorporated in the station design. Existing structures are in fair visual condition. Other nearby land is undeveloped. The site is not visible from nearby public roads, but is visible from other portions of the existing business.

A conceptual layout of this station is shown in Figure 4.5-49. The Raynham Park Station would be a center platform style (Figure 4.5-40) accessed by a passenger crossover (pedestrian bridge and stairs) approximately 23 feet tall. The station would favorably affect the visual environment by replacing some of the existing parking lot and development with a new canopy, platform, and parking lot. The station would be visible to users and occupants of the adjacent buildings, but not to passers-by on Route 138. Its appearance would be an improvement over the nearby developed visual environment, but would be in contrast to nearby undeveloped land. Impacts to the visual environment in the vicinity of the Raynham Park Station would be minimal.

Stoughton Station

The Stoughton Station would be a new train station constructed along the Stoughton Line, west of the existing railroad tracks and north of Brock Street, which would serve all Build Alternatives. In order to

accommodate a second track, the existing Stoughton station would be shifted from its present location between Porter and Wyman streets to a new location south of the Wyman Street at-grade crossing.

A conceptual layout of this station is shown in Figure 4.5-50. The station design type would be a two side platforms (an inbound and outbound platform), each with a canopy, connected by a vertical circulation pedestrian bridge approximately 23 feet tall. The station would be visible from the rear of businesses along Washington Street (Route 138) and Morton Street, and from the rear of approximately five residences along Morton Street and Brock Street. Views of the station from other residences along Morton Street would be screened by trees. The primary view of the station would be from Brock Street at the station driveway. Its appearance would be in keeping with the surrounding visual environment, and impacts to the visual environment would be minimal.

Taunton Station (Stoughton Alternatives)

The Taunton Station would be a new train station constructed along the Stoughton Line that would only serve the Stoughton Alternatives. It would be located near the intersection of East Arlington Street and William Hooke Lane in Taunton.

The Taunton Station site is a previously developed parcel surrounded by commercial development. This location is near a former (historic) train station. The site currently contains vacant buildings and other derelict areas as a result of fire; all are in poor visual condition. The site is visible from nearby roads and residences, and partially visible from sports fields on the opposite (east) side of the tracks.

A conceptual layout of this station is shown in Figure 4.5-51. The Taunton Station would be a side platform style (Figure 4.5-39). The station would favorably affect the visual environment by replacing the existing vacant and derelict structures with a new canopy, platform, and parking lot. The station would be visible to users, occupants of nearby properties, and passers-by. Impacts to the visual environment in the vicinity of the Taunton Station would be very beneficial.

Taunton Depot Station

The Taunton Depot Station (formerly referred to as East Taunton (North) Station) would be a new train station constructed along the New Bedford Main Line that would serve all Build Alternatives. It would be located at 872 County Street in Taunton, behind the existing Target plaza.

The Taunton Depot Station site is an undeveloped parcel adjacent to commercial development and undeveloped lands. Much of the site has been cleared of trees but is vegetated with shrubs and grasses. The adjacent shopping plaza contains numerous retail establishments and is in good visual condition. This site, at the rear of the shopping plaza, is not visible from nearby roadways or the plaza parking lot or stores, and is not visible from other sides due to the forest cover.

A conceptual layout of this station is shown in Figure 4.5-52. The Taunton Depot Station would be a center platform style (Figure 4.5-40). The station would replace the existing vacant lot with a new canopy, platform, and parking lot. The center platform would be accessed by a passenger crossover (pedestrian bridge and stairs), approximately 23 feet tall. The station would be visible to users but generally not to passers-by or other building occupants because of lack of vantage points. Only minor impacts to the visual environment would result from constructing the Taunton Depot Station.

Whale's Tooth Station

The Whale's Tooth Station would be a new train station constructed along the New Bedford Main Line constructed to serve all Build Alternatives. It would be located near the intersection of Acushnet Avenue and Hillman Street, near the southern terminus of the New Bedford Main Line.

The Whale's Tooth Station site is at an existing parking lot surrounded by industrial development. The site is visible from adjacent roads and properties, as well as nearby residences at higher elevations.

A conceptual layout of this station is shown in Figure 4.5-53. The Whale's Tooth Station would be a side platform style (Figure 4.5-39). The station would minimally affect the visual environment with a new canopy and platform constructed at the existing parking lot. The lot would be modified to include accessible spaces near the station platform, a pick-up/drop off area for buses and kiss & ride, and to provide better connections to Acushnet Avenue. The station would be visible to users, occupants of nearby properties, and passers-by. Its appearance would be in keeping with the surrounding developed visual environment. Impacts to the visual environment in the vicinity of the Whale's Tooth Station would be minimal.

Layover Facilities

The Build Alternatives would require midday storage in the Boston area. The mid-day train layover facility is being investigated separately as part of the South Station Expansion Project. Two train layover facilities are planned for the Southern Triangle: one each at or near the end of the Fall River Secondary and the New Bedford Main Line. Three alternative sites were identified for the Fall River Secondary, and two alternative sites were identified for the New Bedford Main Line. The Weaver's Cove East site was selected as the preferred layover facility site for the Fall River Secondary and the Wamsutta site was selected as the preferred layover facility site for the for the New Bedford Line. This section provides basic descriptions of each layover facility site, an indication of its location in reference to the existing visual environment, and a discussion about the visual impacts potentially resulting from constructing these facilities for the South Coast Rail project.

Layover facility plans are conceptual at this point, consisting only of general layouts and footprints. Tracks at the train layover facilities would diverge from the respective through lines (Fall River Secondary, or New Bedford Main Line) and consist of a series of short parallel spurs upon which trains would be parked for overnight layovers and light maintenance work. Parking areas for employees would be included within the facilities, and hooded lights would minimize light pollution. Small site structures are planned for storage and personnel change rooms. The facilities would be fenced and lighted for security. Engineering plans will be completed for these facilities once the LEDPA has been determined.

Wamsutta Layover Facility

The Wamsutta site layover facility would be constructed along the New Bedford Main Line and would serve all rail alternatives. It would be located in New Bedford near the intersection of Wamsutta Street and Herman Melville Boulevard, near the southern terminus of the New Bedford Main Line, just north of the Whale's Tooth Station.

The Wamsutta site is a previously developed site, currently used as a rail yard for CSX, within an industrial area. The site is visible from adjacent roads and buildings. Adjoining properties are transportation corridors or industrial in nature. Industrial sites are located north, east, and south of this

location, and Route 18 to the west. No commercial or residential properties, or open spaces, are located in close proximity to this site. A conceptual layout of a layover facility at the Wamsutta site is shown in Figure 4.5-54.

The Wamsutta site layover facility would minimally affect the visual character of this developed area, continuing its railroad use. The facility would be visible to occupants of nearby properties and passers-by. Its appearance would be in keeping with the surrounding industrial developed visual environment. The proposed new layover facility would not appreciably alter the visual environment given that the site is in an industrial setting partially occupied by an existing rail yard.

Weaver's Cove East Layover Facility

The Weaver's Cove East site layover facility would be constructed along the Fall River Secondary and would serve all rail alternatives. It would be located in Fall River west of Main Street between the existing Fall River Secondary and Main Street, approximately 2.5 miles from the southern terminus of the Fall River Secondary.

The proposed Weaver's Cove East layover facility site is an undeveloped parcel adjoining an abandoned industrial facility and across a primary surface street from a residential neighborhood. Currently vacant land, a portion of the Weaver's Cove East site was previously developed. Approximately one-half of the site is cleared of vegetation or includes remnant building foundations; the remainder of the site is vegetated. Surrounding land to the north, east, and south is residential; industrial land use is present to the southwest. Undeveloped land is immediately west of the site, adjoining the Taunton River. The industrial site to the southwest is a former Shell Oil facility, and consists of completely cleared land with several large aboveground storage tanks and a short shipping dock. The layover facility site is visible from the adjacent residential properties. The layover facility would also be visible from the Taunton River, but partially obscured from view by vegetation. As described above, this segment of the Taunton River has been designated as a "recreational river area," recognizing its aesthetic value and developed shoreline. A conceptual layout of a layover facility at the Weaver's Cove East site is shown in Figure 4.5-55.

The visual environment of the recreational river area would be permanently altered by the new layover facility, but the visual character of this partially developed shoreline would not be adversely affected. The facility construction activities would temporarily adversely impact the visual character of the river in this segment.

The Weaver's Cove East site layover facility would substantially affect the visual environment in this partially developed area. The facility would be visible to occupants of nearby properties and to passers-by on Main Street. The layover facility would be partially visible to passers-by on the Taunton River. Its appearance would be in keeping with the existing developed industrial visual environment but in contrast to adjacent residential and undeveloped land. It may adversely affect the visual setting of the North Main Street District of Fall River.

4.5.4 Summary of Impacts by Alternative

This section summarizes the direct effects to visual and aesthetic resources potentially resulting from implementing each of the South Coast Rail project alternatives, based upon conceptual engineering plans.

The individual components of each element are grouped by alternative, and the expected impacts to the surrounding visual environment are summarized based upon a qualitative assessment of the change in the visual character of the local environment that would result from each component combined with the actual visibility of those changes. The visual impacts of each element are rated as substantial, moderate, or minimal, based upon a qualitative generalization of how easily and frequently the changed visual environment may be seen by occupants of adjacent or nearby properties (including residences and businesses), recreationists on adjacent open space, or passers-by on sidewalks, roads, highways or water bodies. This evaluation does not take into consideration the perspective of passengers on the trains or buses.

4.5.4.1 Stoughton Electric Alternative

The Stoughton Electric Alternative (Figure 1.4-4) would be comprised of the elements listed in Table 4.5-1, which also summarizes the direct effects to visual and aesthetic resources potentially resulting from implementing this alternative.

In general, the Stoughton Electric Alternative presents moderate impacts to the visual environment. The visual impacts would vary locally and by individual component, but this alternative would use existing infrastructure (upgraded as necessary) only to a moderate degree. Where existing infrastructure is used, most impacts to the visual environment would be incremental additions to an existing, disturbed landscape with active rail use. The out-of-service portion of the Stoughton Line segment, from the Stoughton Station south to Weir Junction, would require railroad reconstruction and new electrical infrastructure construction with attendant substantial impacts to the visual environment. Vegetation removal would change the visual character for residential neighborhoods and open spaces along this portion of the Stoughton Line. In some portions of this segment, and at some of the station sites, the visual impact is partially offset by the low visibility of these sites, in somewhat remote locations, to the general public. The visual character in the vicinity of the historic district in Easton would be substantially affected by the re-established train service and new Easton Village Station.

Table 4.5-1 Summary of Potential Direct Effects to Visual and Aesthetic Resources from the Stoughton Electric Alternative

Element/Component	Change in Visual Environment	Visual Impact
Railroad Alignments		
Northeast Corridor	No new construction	None
Stoughton Line	Track, crossing, and electrical infrastructure upgrades in active, disturbed environment and new track, trestle, crossing, and electrical infrastructure construction in out-of-service railroad corridor, including urban and rural settings, and four crossings of a designated "Wild and Scenic River" with overhead catenary system	Moderate to Substantial
Fall River Secondary	Track and crossing upgrades, and electrical infrastructure construction in active, disturbed environment including rural and urban settings, and one crossing of a designated "Wild and Scenic River" with overhead catenary system	Moderate
New Bedford Main Line	Track and crossing upgrades, and electrical infrastructure construction in active, disturbed environment including rural and urban settings	Moderate
Stations		
Canton Center	Station reconstruction in developed area	Minimal
Stoughton	New station construction in developed area	Minimal
North Easton	New station construction in partially developed/ undeveloped area	Minimal
Easton Village	New station construction in partially developed/ undeveloped area	Substantial
Raynham Park	New station construction in developed area	Minimal
Taunton	New station construction in developed area	Moderate (beneficial)
Taunton Depot	New station construction in partially developed/ undeveloped area	Minimal
Freetown	New station construction in partially developed/ undeveloped area	Minimal
Fall River Depot	New station construction in developed area	Moderate (beneficial)
Battleship Cove	New station construction in developed area	Minimal
King's Highway	New station construction in developed area	Minimal
Whale's Tooth	New station construction in developed area	Minimal
Layover Facility Alternatives		
Wamsutta Site	New facility construction in developed area	Minimal
Weaver's Cove East Site	New facility construction in partially developed area, including designated "Wild and Scenic River"	Moderate

4.5.4.2 Stoughton Diesel Alternative

The Stoughton Diesel Alternative would be comprised of the same elements as the Stoughton Electric Alternative (shown in Figure 1.4-4) as listed above but would not need electrical infrastructure. Specifically, the metal structures and wires associated with the overhead catenary system, and the traction power facilities, would not be constructed as part of this alternative. Table 4.5-2 summarizes the direct effects to visual and aesthetic resources potentially resulting from implementing this alternative.

In general, the Stoughton Diesel Alternative also presents moderate impacts to the visual environment, but less of an impact than the electric alternative because there would not be electric infrastructure along the alignment. As with the Stoughton Electric Alternative, the visual impacts would vary locally

and by individual component. Where existing infrastructure is used, most impacts to the visual environment would be incremental additions to an existing, disturbed landscape with active rail use. The out-of-service portion of the Stoughton Line segment, from the Stoughton Station south to Weir Junction, would require significant railroad reconstruction with attendant significant impacts to the visual environment. Vegetation removal would change the visual character for residential neighborhoods and open spaces along this portion. In some portions of this segment, and at some of the station sites, the visual impact is partially offset by the low visibility of these sites, in somewhat remote locations, to the general public. The visual character in the vicinity of the historic district in Easton would be substantially affected by the re-established train service and new Easton Village Station.

Table 4.5-2 Summary of Potential Direct Effects to Visual and Aesthetic Resources from the Stoughton Diesel Alternative

Element/Component	Change in Visual Environment	Visual Impact
Railroad Alignments		
Northeast Corridor	No new construction	None
Stoughton Line	Track and crossing upgrades in active, disturbed environment and new track, trestle and crossing construction in out-of-service railroad corridor, including urban and rural settings, and four crossings of a designated "Wild and Scenic River"	Minimal to Substantial
Fall River Secondary	Track and crossing upgrades in active, disturbed environment including rural and urban settings, and one crossing of a designated "Wild and Scenic River"	Minimal
New Bedford Main Line	Track and crossing upgrades in active, disturbed environment including rural and urban settings	Minimal
Stations		
Canton Center	Station reconstruction in developed area	Minimal
Stoughton	New station construction in developed area	Minimal
North Easton	New station construction in partially developed/ undeveloped area	Minimal
Easton Village	New station construction in partially developed/ undeveloped area	Substantial
Raynham Park	New station construction in developed area	Minimal
Taunton	New station construction in developed area	Moderate (beneficial)
Taunton Depot	New station construction in partially developed/ undeveloped area	Minimal
Freetown	New station construction in partially developed/ undeveloped area	Minimal
Fall River Depot	New station construction in developed area	Moderate (beneficial)
Battleship Cove	New station construction in developed area	Minimal
Stations		
King's Highway	New station construction in developed area	Minimal
Whale's Tooth	New station construction in developed area	Minimal
Layover Facility Alternatives		
Wamsutta Site	New facility construction in developed area	Minimal
Weaver's Cove East Site	New facility construction in partially developed area, including designated "Wild and Scenic River"	Moderate

No new electrical infrastructure construction (overhead catenary system and traction power facilities) would be needed. This reduces the overall visual impact of the Stoughton Diesel Alternative as compared to the Stoughton Electric Alternative.

4.5.4.3 Whittenton Electric Alternative

The Whittenton Electric Alternative would be comprised of the elements listed in Table 4.5 3, which also summarizes the direct effects to visual and aesthetic resources potentially resulting from implementing this alternative.

Table 4.5-3 Summary of Potential Direct Effects to Visual and Aesthetic Resources from the Whittenton Electric Alternative

Element/Component	Change in Visual Environment	Visual Impact
Railroad Alignments		
Northeast Corridor	No new construction	None
Stoughton Line	Track, crossing, and electrical infrastructure upgrades in active, disturbed environment and new track, trestle, crossing, and electrical infrastructure construction in out-of-service railroad corridor, including urban and rural settings	Moderate to Substantial
Whittenton Branch	New track, crossing, and electrical infrastructure construction in out-of-service railroad corridor, including urban and rural settings	Moderate
Attleboro Secondary	Track and crossing upgrades, and electrical infrastructure construction in active, disturbed environment including rural and urban settings	Moderate
Fall River Secondary	Track and crossing upgrades, and electrical infrastructure construction in active, disturbed environment including rural and urban settings, and one crossing of a designated “Wild and Scenic River” with overhead catenary system	Moderate
New Bedford Main Line	Track and crossing upgrades, and electrical infrastructure construction in active, disturbed environment including rural and urban settings	Moderate
Stations		
Canton Center	Station reconstruction in developed area	Minimal
Stoughton	New station construction in developed area	Minimal
North Easton	New station construction in partially developed/ undeveloped area	Minimal
Easton Village	New station construction in partially developed/ undeveloped area	Substantial
Raynham Park	New station construction in developed area	Minimal
Dana Street	New station construction in developed area	Minimal
Taunton Depot	New station construction in partially developed/ undeveloped area	Minimal
Freetown	New station construction in partially developed/ undeveloped area	Minimal
Fall River Depot	New station construction in developed area	Moderate (beneficial)
Battleship Cove	New station construction in developed area	Minimal
King’s Highway	New station construction in developed area	Minimal
Whale’s Tooth	New station construction in developed area	Minimal
Layover Facility Alternatives		
Wamsutta Site	New facility construction in developed area	Minimal
Weaver’s Cove East Site	New facility construction in partially developed area, including designated “Wild and Scenic River”	Moderate

In general, the Whittenton Electric Alternative presents a moderate impact to the visual environment. As with the Stoughton Electric Alternative, the visual impacts would vary locally and by individual component, but this alternative would use existing infrastructure (upgraded as necessary) only to a moderate degree. Where existing infrastructure is used, most impacts to the visual environment would be incremental additions to an existing, disturbed landscape with active rail use. The out-of-service portion of the Stoughton Line and Whittenton Branch segments, from the Stoughton Station south to Raynham Junction and on to Whittenton Junction, would require railroad reconstruction and new electrical infrastructure construction with attendant significant impacts to the visual environment.

Vegetation removal would change the visual character for residential neighborhoods and open spaces along this portion. In some portions of this segment, and at some of the station sites, the visual impact is partially offset by the low visibility of these sites, in somewhat remote locations, to the general public. The visual character in the vicinity of the historic district in Easton would be substantially affected by the re-established train service and new Easton Village Station.

4.5.4.4 Whittenton Diesel Alternative

The Whittenton Diesel Alternative would be comprised of the same elements as the Whittenton Electric Alternative as listed above but would not need electrical infrastructure. Specifically, the metal structures and wires associated with the overhead catenary system, and the traction power facilities, would not be constructed as part of this alternative. Table 4.5-4 summarizes the direct effects to visual and aesthetic resources potentially resulting from implementing this alternative.

In general, the Whittenton Diesel Alternative also presents a moderate impact to the visual environment, but less of an impact than the electric alternative because there would not be electric infrastructure along the alignment. As with the Stoughton Diesel Alternative, the visual impacts would vary locally and by individual component. Where existing infrastructure is used, most impacts to the visual environment would be incremental additions to an existing, disturbed landscape with active rail use. The out-of-service portion of the Stoughton Line and Whittenton Branch segments, from the Stoughton Station south to Raynham Junction and on to Whittenton Junction, would require railroad reconstruction with attendant significant impacts to the visual environment. Vegetation removal would change the visual character for residential neighborhoods and open spaces along this portion. In some portions of this segment, and at some of the station sites, the visual impact is partially offset by the low visibility of these sites, in somewhat remote locations, to the general public. The visual character in the vicinity of the historic district in Easton would be substantially affected by the re-established train service and new Easton Village Station.

No new electrical infrastructure construction (overhead catenary system and traction power facilities) would be needed. This reduces the overall visual impact of the Whittenton Diesel Alternative as compared to the Whittenton Electric Alternative.

Table 4.5-4 Summary of Potential Direct Effects to Visual and Aesthetic Resources from the Whittenton Diesel Alternative

Element/Component	Change in Visual Environment	Visual Impact
Railroad Alignments		
Northeast Corridor	No new construction	None
Stoughton Line	Track and crossing upgrades in active, disturbed environment and new track, trestle, and crossing construction in out-of-service railroad corridor, including urban and rural settings	Moderate to Substantial
Whittenton Branch	New track and crossing construction in out-of-service railroad corridor, including urban and rural settings	Moderate
Attleboro Secondary	Track and crossing upgrades in active, disturbed environment including rural and urban settings	Minimal
Fall River Secondary	Track and crossing upgrades in active, disturbed environment including rural and urban settings, and one crossing of a designated “Wild and Scenic River”	Minimal
New Bedford Main Line	Track and crossing upgrades in active, disturbed environment including rural and urban settings	Minimal
Stations		
Canton Center	Station reconstruction in developed area	Minimal
Stoughton	New station construction in developed area	Minimal
North Easton	New station construction in partially developed/ undeveloped area	Minimal
Easton Village	New station construction in partially developed/ undeveloped area	Substantial
Raynham Park	New station construction in developed area	Minimal
Dana Street	New station construction in developed area	Minimal
Taunton Depot	New station construction in partially developed/ undeveloped area	Minimal
Freetown	New station construction in partially developed/ undeveloped area	Minimal
Fall River Depot	New station construction in developed area	Moderate (beneficial)
Battleship Cove	New station construction in developed area	Minimal
King’s Highway	New station construction in developed area	Minimal
Whale’s Tooth	New station construction in developed area	Minimal
Layover Facility Alternatives		
Wamsutta Site	New facility construction in developed area	Minimal
Weaver’s Cove East Site	New facility construction in partially developed area, including designated “Wild and Scenic River”	Moderate

4.5.4.5 Summary of Impacts

The overall impacts to visual and aesthetic resources resulting from improving or constructing the Build Alternatives would not vary considerably between the alternative alignments. Although all alternatives are rated with an overall moderate visual impact, each alternative alignment has at least one element with a substantial visual impact at the local level. The Stoughton and Whittenton Alternatives would substantially impact the visual environment at the historic Easton train station and in currently out-of-service segments of the Stoughton Line and Whittenton Branch for some 15 miles. Public views of the proposed 1.6-mile trestle would be limited throughout the Hockomock Swamp wildlife management area and will have a visual impact; however there is limited public access to this area. Electric alternatives would have higher visual impacts than diesel alternatives due to the electrical infrastructure requirements.

4.5.5 Mitigation

4.5.5.1 Introduction

This section summarizes the mitigation measures that may be taken to minimize the visual impact resulting from the South Coast Rail project alternatives.

4.5.5.2 Potential Mitigation Measures

Generally, mitigation is appropriate where facilities are most visible and present a change to the existing visual environment, but are not outweighed by safety considerations. Mitigating impacts to the visual environment generally involves screening a facility or structure, or blending its design with the surrounding environment.

The project has the potential to alter the aesthetics of certain properties and districts where new stations, parking lots, or crossings are proposed. While the original construction of any of the railroads in the mid-1800s may have been consistent with the aesthetic nature of the communities at that time, reactivating the rail lines using modern materials and safety standards may result in undesirable changes in the visual environment. Screening certain structures and safety and signal equipment may mitigate these impacts. Potential screening techniques include the combination of wooden and opaque chain link fencing with landscape plantings.

The proposed visual mitigation measures include siting and designing facilities to minimize changes to the visual landscape, and minimizing vegetation removal along the right-of-way. Mitigation measures such as screening and light minimization would be incorporated during preliminary or final design. The specific mitigation measures proposed for visual impacts are listed in Table 4.5-5 and the following subsections outline these approaches for each element of the alternatives.

Table 4.5-5 Proposed Mitigation Measures for Potential Impacts to Visual and Aesthetic Resources

Potential Mitigation Measure	Implementation Schedule
Install screening in selected locations	During construction
Select station lighting fixtures, designs, and technologies that minimize night sky impacts	During design
Install station lighting that minimizes night-sky impacts	During construction
Design facilities and structures to blend with the surrounding landscape	During design

Screening

Facilities or structures may be screened from view by natural or man-made barriers. Typically, the choice of a screening method is based upon the surrounding environment: natural visual barriers, such as vegetation screens, are best suited to natural environments. Physical placement of the facilities, removed from view by the majority of the general public, can also function as a form of screening. Man-made barriers, such as walls or fences, function well in a built environment. Vegetation may also be suitable within the built environment if the surrounding properties include landscaping elements.

Unnecessary clear-cutting of trees and vegetation along the railroad rights-of-way that would have an adverse visual impact on residential properties or open spaces would be avoided. Existing trees and

vegetative screening would be retained to visually buffer properties from the rail lines to the extent feasible and with due regard for public safety, operational requirements, cost, and maintenance considerations.

Screening is most applicable for facilities with a vertical component, such as stations and electrical infrastructure, as compared to the railroad track itself. Although the stations must be placed along the railroad or highway alignments, their locations along those alignments have often been chosen to minimize the visual impact by siting behind existing structures or remote from passers-by. Remote locations for traction power facilities have similarly been chosen, and these facilities can be further screened from passengers' view by vegetation or other screening. The overhead catenary systems, however, cannot be screened from view except by the unrelated routing of the railroad line in remote locations.

Design

Facilities or structures may also be designed to blend with the surrounding visual environment. This can be accomplished by designing architecturally consistent or unobtrusive structures. For example, the proposed replacement bridges over segments of the Taunton River that are designated as "scenic" or "recreational" river areas are envisioned as architecturally consistent with the existing bridges and visual environment. Station platforms and weather shelters, on the other hand, are unobtrusive structures that fit well in most built environments. Facilities proposed for industrial locations, such as the Wamsutta and Church Street site layover facilities, would blend well with the surrounding visual environment due to the appearance of the nearby industrial facilities.

Where prudent, equipment including traffic signals and controller cabinets, street lights, street furniture, overhead catenary system poles, and railroad signal equipment housings would be dark colored to reduce the visual impact of this equipment. Special design of a low visual impact overhead catenary system would be considered where appropriate. Traffic signals and street lights would be ornamental type in accordance with the towns' preferences to the extent reasonably possible, and would feature downward-facing hoods to minimize light pollution.

4.5.5.3 Summary

Screening and design methods could successfully reduce and mitigate some potential visual impacts to properties associated with the reactivation of any of the historic railroads for the South Coast Rail project. Impacts would be minimized by siting the power substations and stations where they would reduce changes to the visual landscape, and lighting has been selected to minimize night-sky impacts. However, visual impacts cannot be completely avoided for any alternative.

Additional mitigation measures will be explored in the final design, for the LEDPA.

4.5.6 Regulatory Compliance

This section outlines the regulatory compliance requirements for visual and aesthetic resources. These resources are indirectly regulated at the federal or state levels, and are usually considered in NEPA or MEPA analyses. Compliance with the National Historic Preservation Act typically includes assessment of the visual context of a cultural resource, as discussed separately in Chapter 4.8, *Cultural Resources*. The only other applicable federal law with specific reference to visual resources is the Wild and Scenic Rivers Act. As discussed in the section on the Southern Triangle, the Taunton River was recently included in the Wild and Scenic River Program.

4.5.6.1 Wild and Scenic Rivers Act

Section 2(b) of the 1968 Wild & Scenic Rivers Act specifies that river segments may be classified, designated, and administered as wild river areas, scenic river areas, or recreational river areas. These determinations are based essentially on the degree of naturalness and access to the river. The Act is administrated by the U.S. Department of the Interior (USDOI National Park Service), except on U.S. Department of Agriculture (USDA) Forest Service properties, which are administered by the Forest Service. The National Park Service administrates the Wild and Scenic River Program generally, and the Forest Service administrates the program within properties managed by that agency. The National Park Service refers to Forest Service regulations, published in 36 CFR, to implement the Act and is the lead agency for this program as it relates to the South Coast Rail project's potential impacts to visual resources along the Taunton River. On March 30, 2009, segments of the Taunton River were designated as "scenic" or "recreational" river areas under the Wild and Scenic Rivers Act; on that date, the segment along the Fall River Secondary and the segment through Taunton from Weir Street to Route 24 were designated as a "recreational river area," which is defined by the Act as a segment with a partially developed shoreline and ready access.

Consultation

USDA implementing regulations, at 36 CFR 297.4, state that "[n]o license, permit, or other authorization can be issued for a Federally assisted water resources project on any portion of a Wild and Scenic River or Study River nor can appropriations be requested to begin construction of such projects, without prior notice to the Secretary of Agriculture, and a determination in accordance with section 7 of the Act."

Additionally, "[f]ederal assistance means… a license, permit, or other authorization granted by the ACOE pursuant to the Rivers and Harbors Act and section 404 of the Clean Water Act" (36 CFR 297.3).

Finally, "[t]he Secretary of Agriculture will consent to the issuance of any Federal license, permit, or other authorization if, as a finding of fact, it is determined that: (1) the water resources project will not have a direct and adverse effect on the values for which a Wild and Scenic River or Study River was designated, when any portion of the project is within the boundaries of said river, or; (2) the effects of the water resources project will neither invade nor unreasonably diminish the scenic, recreational, and fish or wildlife values of a Wild and Scenic River, when any portion of the project is located above, below, or outside the Wild and Scenic River… if consent is denied, the Secretary may recommend measure to eliminate adverse effects, and the authorizing agencies may submit revised plans for consideration" (36 CFR 297.5).

A Clean Water Act Section 404 permit is required for discharge of fill material incidental to bridge construction if the piers, supports or other infrastructure for such bridge are proposed to be placed in waters of the United States. These conditions apply to construction of replacement bridges over the Taunton River and the layover facilities adjacent to the river, which therefore would require a Clean Water Act Section 404 permit. Consultation with the National Park Service would be necessary to obtain the Secretary of Agriculture's concurrence that the effects of the South Coast Rail project on the recreational values of the Taunton River would be neither invaded nor unreasonably diminished.

The following sections summarize the applicability of this consultation requirement for each South Coast Rail alternative.

Stoughton Alternatives

The Stoughton Alternatives also include the New Bedford Main Line, which crosses the Taunton River just south of Weir Junction. The Stoughton Line also crosses the Taunton River at three locations north of Weir Junction, as well as a tributary to the Taunton River (the Mill River) within 0.25 mile of the Taunton River's main stem. Bridge replacement at all of these locations, as described in the Southern Triangle and Stoughton Electric Alternative sections, would affect the visual environment of the Taunton River as regulated by the National Park Service under the Wild and Scenic Rivers Act. The layover facility site along the Fall River Secondary (Weaver's Cove East) also would affect the visual environment of the Taunton River. The National Park Service was contacted for consultation. A meeting between MassDOT and representatives from the NPS Wild and Scenic Rivers Program was held in January 2012 to discuss the status of Taunton River as a National Wild and Scenic River. Detailed descriptions of the South Coast Rail project's potential impacts to the Taunton River from the proposed bridge replacement and Fall River Depot Station were requested. These are described above in Section 4.5.3.3 in the context of visual resources, and are also summarized in Chapter 4.10, *Open Space*. This chapter also provides information regarding the layover facility along the Fall River Secondary. Further consultation with NPS is anticipated as the project advances through the design process.

Whittenton Alternatives

The Whittenton Alternatives also include the New Bedford Main Line, which crosses the Taunton River just south of Weir Junction. These alternatives, however, follow the Attleboro Secondary for a brief distance north of Weir Junction, bypassing the Taunton River crossings of the Stoughton Alternatives. Bridge replacement at the single New Bedford Main Line crossing (described in the Southern Triangle section) would affect the visual environment of the Taunton River as regulated by the National Park Service under the Wild and Scenic Rivers Act. The Weaver's Cover East layover facility site along the Fall River Secondary also would affect the visual environment of the Taunton River. The National Park Service has been contacted for consultation as described above for the Stoughton Alternative.

4.6 NOISE

4.6.1 Introduction

This chapter describes the noise analysis methodology, noise assessment criteria, existing noise levels, noise impacts and mitigation measures.

4.6.1.1 Resource Definition

Noise is defined as unwanted or excessive sound. Sound becomes unwanted when it interferes with normal activities, such as sleep, work, or recreation. Under extreme conditions sound can cause physical harm, such as hearing loss or adverse mental health effects. Although there are no specific state or federal statutes or regulations concerning transit noise, MEPA and NEPA require evaluating noise impacts as part of a proposed project's potential impacts on the human environment.

How people perceive sound depends on the following measurable physical characteristics of the sound.

- **Intensity**: Sound intensity is often equated to loudness. The sound level magnitude (typically measured in decibels [dB]) is a measure of sound intensity. A 10-decibel increase in intensity is generally perceived as a doubling in loudness.

- **Frequency Content**: Most common sounds are composed of acoustic energy distributed over a variety of frequencies. Acoustic frequencies, commonly referred to as tone or pitch, are typically measured in Hertz (Hz). High-frequency (above 2,000 Hz) sound is typically considered more annoying than low-frequency (below 500 Hz) sound and may also be perceived as louder.

- **Temporal Pattern**: The temporal nature of sound includes factors such as continuity, fluctuation, impulsiveness, and intermittence. Sound with increasing intensity over time is often perceived as louder than sound with decreasing intensity. Impulsive and intermittent sounds are usually perceived as louder than the actual sound level.

Individual human response to noise is subject to considerable variability. There are many factors, both emotional and physical, that contribute to the variation in human reaction to noise. The existence of numerous emotional and physical variables prohibits defining an exact individual or community response for any given noise level. Community noise criteria are therefore based on statistical averages of human response to noise and applicable health criteria.

Sound levels are most often measured using decibels (dB). The dB scale is logarithmic and compresses the audible acoustic pressure levels, which can vary from 20 micropascals (µPa), the reference pressure and threshold of hearing (0 dB), to 20 million µPa, the threshold of pain (120 dB). Because the dB scale is logarithmic, the addition of two sound levels is not linear. To add sound levels in dB, the dB are converted into energy terms, which are then added and converted back to dB.

The human ear does not hear sound energy linearly (on a one-to-one basis); hence, humans do not perceive changes in sound level as equally loud. Research indicates that the following general relationships exist between sound level and human perception:

- A 3 dB increase is a doubling of acoustic energy. Studies have shown that 3 dB is the threshold for people to perceive a change in sound level. The average person will not be able to distinguish a 3 dB difference in sound level in a laboratory condition; and
- A 10 dB increase is a tenfold increase in acoustic energy but is perceived as a doubling in loudness to the average person. The average person will judge a 10 dB change in sound level to be twice or half as loud.

The human ear does not perceive sound levels from every frequency as equally loud. As part of the hearing process, the human ear will attenuate low and high-frequency sounds. To compensate for these phenomena in perception, the A-weighted decibel scale, referred to as dBA, is used to measure and evaluate environmental noise levels. The A-weighted scale adjusts sound pressure levels by frequency, reducing low and high-frequency sound, similar to the way people hear sound. All of the sound levels used to evaluate noise impacts associated with this project are in dBA. Table 4.6-1 illustrates the decibel levels for typical indoor and outdoor sound.

The most commonly used indicators for community noise surveys are the energy-averaged equivalent sound level (Leq) and the day-night averaged sound level (Ldn). This noise analysis uses Ldn and Leq sound levels to evaluate noise. The Leq and the Ldn are the most frequently used metrics in environmental noise analyses. Extensive federal research has concluded that the Leq and Ldn are the best metrics for determining annoyance (impact) to the human environment. The Ldn is currently the predominant noise metric used by most federal agencies, including the FTA, USEPA, Federal Aviation Administration, Department of Housing and Urban Development, and Department of Defense.

The Leq is the steady-state sound level, which in a given period of time (typically one hour) contains the same acoustic energy as the time-varying (fluctuating) sound level during that same period. The Leq averages the background sound levels with short-term transient sound levels. The background sound level does not include noise from transient events (such as aircraft over-flights) and typically fluctuates during the day, week, and year. The 1-hour average Leq is implied throughout this analysis when the term Leq is used. The Ldn noise indicator is a 24-hour average sound level that is derived from hourly Leq values with a 10 dBA penalty on sounds occurring at night (10pm to 7am). The peak hour Leq represents the noisiest hour of the day or night and usually occurs during the peak periods of automobile and truck traffic.

4.6.2 Existing Conditions

4.6.2.1 Methodology

The FTA Transit Noise and Vibration Impact Assessment Guidelines[1] were used to evaluate existing noise conditions. These guidelines specify criteria and define procedures to project transit noise exposure.

The FTA guidelines require that noise-sensitive locations within impact distances to the rail corridor be categorized into three types of noise-sensitive land uses. The three land use categories correlate land use with sensitivity to noise intrusions and reflect the various noise-sensitive land uses, which could be present along the proposed rail corridor. The land use categories are presented in Table 4.6-2.

[1] Transit Noise and Vibration Impact Assessment, Federal Transit Administration, May 2006

Table 4.6-1 Typical Indoor and Outdoor Sound Levels

Outdoor Sound Levels	Sound Pressure[1] (μPa)	Sound Level[2] (dBA)	Indoor Sound Levels
Threshold of pain	20,000,000	120	
		115	
	6,324,555	110	Rock band at 5 meters (m)
Jet Over-Flight at 300 m		105	
	2,000,000	100	Inside New York subway train
Gas Lawn Mower at 1 m		95	
	632,456	90	Food blender at 1 m
Diesel Truck at 15 m		85	
Noisy Urban Area—Daytime	200,000	80	Garbage disposal at 1 m
		75	Shouting at 1 m
Gas Lawn Mower at 30 m	63,246	70	Vacuum cleaner at 3 m
Suburban Commercial Area		65	Normal speech at 1 m
	20,000	60	
Quiet Urban Area—Daytime		55	Quiet conversation at 1 m
	6,325	50	Dishwasher next room
Quiet Urban Area—Nighttime		45	
	2,000	40	Empty theater or library
Quiet Suburb—Nighttime		35	
	632	30	Quiet bedroom at night
Quiet Rural Area—Nighttime		25	Empty concert hall
Rustling Leaves	200	20	
		15	Broadcast and recording studios
	63	10	
		5	
Threshold of hearing	20	0	

Source: Highway Noise fundamentals, Federal Highway Administration, 1980
1 Micropascals (μPa) describe pressure levels, which is what sound level monitors measure.
2 A-weighted decibels (dBA) describe pressure logarithmically with respect to the reference pressure level of 20 μPa.

Sound levels were measured using a Larsen Davis 824 Type I sound level meter that meets the American National Standards Institute testing specifications. An acoustic calibrator was used to calibrate the sound level meter. The noise monitoring program was conducted on December 18 and December 30, 2008. Sound level data were collected at various locations adjacent to segments of the proposed alternative during weekday daytime period (10:00 A.M. to 5:00 P.M.) and weekday nighttime period (8:00 P.M. to 1:00 A.M.). The sound level data were collected for approximately 20-minute durations at each monitoring location.

Table 4.6-2 Land Use Categories and Metrics for Transit Noise Impact Criteria

Land Use Category	Noise Metric (dBA)	Description of Land Use Category
1	Outdoor Leq(h)[1]	Tracts of land where quiet is an essential element in their intended purpose. This category includes lands set aside for serenity and quiet, and such land uses as outdoor amphitheaters and concert pavilions, as well as National Historic Landmarks with significant outdoor use.
2	Outdoor Ldn	Residences and buildings where people normally sleep. This category includes homes, hospitals and hotels where a nighttime sensitivity to noise is assumed to be of utmost importance.
3	Outdoor Leq(h)[1]	Institutional land uses with primarily daytime and evening use. This category includes schools, libraries, and churches where it is important to avoid interference with such activities as speech, meditation and concentration on reading material. Buildings with interior spaces where quiet is important, such as medical offices, conference rooms, recording studios and concert halls fall into this category. Places for meditation or study associated with cemeteries, monuments, museums. Certain historical sites, parks and recreational facilities are also included.

Leq for the noisiest hour of transit-related activity during hours of noise sensitivity.

Both Leq and Ldn sound levels were used to measure existing noise exposure. The noise metric for the land use Categories 1 and 3 in Table 4.6-2 is Leq. The noise metric for land use Category 2 (typically residences) is Ldn. The Ldn sound levels were calculated based upon daytime and nighttime Leq sound levels following the procedures provided in the FTA Transit Noise and Vibration Impact Assessment guidelines.

4.6.2.2 Existing Noise Levels

Existing noise levels were monitored at selected locations along various segments of the proposed alternatives. The noise monitoring sites were selected to provide background sound levels for similar land uses along the rail alternative corridors. Their selection was based upon land uses, accessibility, and reasonable area coverage. Figure 4.6-1 shows the alternatives, the rail and road segments in each alternative, town boundaries, and noise monitoring locations. The noise monitoring field notes are provided in Appendix 4.6-A.

All but one of the locations monitored was in an area of land use Category 2 (residences and buildings where people normally sleep). The exception was Morton Street in Stoughton on the Stoughton Line, which also has some land uses in Category 3 (institutional uses with primarily daytime and evening use).

Existing daytime sound levels (based on Leq), at the locations monitored, range from a low of about 49 dBA to a high of about 69 dBA. The 69-dBA level occurred at Dean Street in Taunton along the Stoughton Line. This sound level is typical of an area located near Route 44, a busy highway passing through an area with some commercial development. Eighteen of the 30 locations have noise levels equivalent to or below that of a quiet urban area in the daytime. Most of the remaining areas are between that level and the level for a suburban commercial area. Table 4.6-3 presents the land use and the results of the noise monitoring at each location.

Table 4.6-3 Existing Noise Levels at Monitoring Locations

4.6.3 Analysis of Impacts and Mitigation

4.6.3.1 Introduction

This section identifies the noise impacts that may result from implementing each of the proposed South Coast Rail alternatives (including railroad or highway alignments, train or bus stations, and maintenance/layover facilities).

The noise evaluation followed FTA guidance for the noise analysis procedures, identifying noise-sensitive receptor locations, noise impact criteria, measuring existing sound levels, calculating future sound levels, establishing impact thresholds, identifying noise impacted locations, and determining potential noise mitigation measures. The noise evaluation included the analysis of train noise (operations and train horn noise at grade-crossings) for the No-Build (Enhanced Bus), Stoughton Electric, Stoughton Diesel, Whittenton Electric, and Whittenton Diesel alternatives. The noise evaluation also analyzed train noise at the proposed train station and at the proposed overnight layover facilities. Specifically, the noise analysis establishes existing sound levels, calculated project-generated sound levels, developed the distances from the train tracks to moderate and severe noise impacts along the rail alternatives, identified impacted residences, and recommends noise mitigation measures.

For locations where noise impacts were identified, mitigation measures, such as noise barriers and sound-proofing, were identified to mitigate for significant adverse effects. In addition, potential noise mitigation measures for construction activities were identified.

The Secretary of the Executive Office of EEA issued a Certificate on the ENF on April 3, 2009.[2] Included in the certificate are a number of requirements defining the scope of the Draft EIR. The following outlines the requirements for the evaluation of noise impacts.

- The DEIR should include an analysis of noise impacts associated with the project alternatives, for locations along the rail and bus routes, and at station sites.
- The DEIR should evaluate measures to avoid and minimize noise impacts, including plantings and other noise barriers. The noise analysis in the DEIR should discuss consistency with applicable state and federal guidelines and regulations.
- The noise analysis should include an assessment of impacts to wildlife which is discussed in Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*.

The Secretary's Certificate on the DEIR[3] included the following requirements for the analysis of noise and vibration.

- "The FEIR should include a detailed evaluation of those locations that will experience moderate and severe noise impacts as a result of the project and commitments to specific mitigation measures."

[2] Massachusetts Executive Office of Energy and Environmental Affairs. Certificate of the Secretary of Energy and Environmental Affairs on the Environmental Notification Form. April 3, 2009.

[3] Massachusetts Executive Office of Energy and Environmental Affairs. Certificate of the Secretary of Energy and Environmental Affairs on the Draft Environmental Impact Report. July 29, 2011.

- "The evaluation should address noise impacts relating to all aspects of the project including train operations and horn noise, and noise associated with stations and layover facilities."
- "MassDOT should consult with MassDEP and the Interagency Coordinating Group for guidance on development of the noise mitigation plan."
- "The FEIR should include a detailed mitigation plan with commitments to an appropriate level of mitigation for project-related noise impacts."
- "The FEIR should document how the project will comply with MassDEP … Noise Policy."
- "The FEIR should compare the estimated vibration levels to existing conditions and describe the actual change that will be experienced. This additional information should be provided for residential impacts along the Stoughton route as well as for historic buildings."
- "The FEIR should include a mitigation plan with clear and specific commitments to address vibration impacts and an explanation of the reduction in VdB levels expected."

Subsequent to the DEIS/DEIR, the MassDOT updated the noise impact analysis for the Stoughton Electric Alternative to take into account design refinements, changes to the operations plan and to provide a more detailed noise impact assessment and mitigation plan as requested by Executive Office of EEA in the Secretary's Certificate on the DEIR. The noise impact and mitigation analyses for the Stoughton Diesel Alternative and the Whittenton (Diesel and Electric) Alternatives remain the same as presented in the DEIS/DEIR.

The following sections discuss the noise evaluation methodology, potential noise impacts by elements, construction noise, and potential noise impacts by alternative. Section 4.6.3.3 describes the background noise as well as the noise impact results for the South Coast Rail elements. Section 4.6.3.4 reviews the potential temporary construction impacts and related mitigation. Section 4.6.3.5 presents a summary of the impacts by each alternative. Section 4.3.3.6 identifies the type and location of the measures required to mitigate potential significant noise impacts.

4.6.3.2 Impact Assessment Methodology

The noise analysis identified potential noise impacts by comparing the existing sound levels to projected future sound levels. The existing sound levels were based upon a noise monitoring program. The FTA Transit Noise and Vibration Impact Assessment Guidelines[4] were used to evaluate existing noise conditions. These guidelines specify criteria and define procedures to project transit noise exposure. Detailed technical documentation of the noise impact assessment for the Stoughton Diesel Alternative and the Whittenton Alternatives is provided in Appendix 4.6-B (the documentation remains the same as was provided in the DEIS/DEIR).

The projected future sound levels were calculated using the FTA rail spreadsheet model. The results were compared to the FTA noise impact criteria discussed below to predict if noise impacts would occur. Once the future noise levels from the proposed project and the potential impacts were assessed, a determination of the need, feasibility, reasonableness, and effectiveness of mitigation measures was conducted. Appendix 4.6-C provides the updated impact assessment and mitigation analysis documentation for the Stoughton Electric Alternative.

[4] Transit Noise and Vibration Impact Assessment, Federal Transit Administration, May 2006.

The FTA guidelines require that noise-sensitive locations within impact distances to the rail corridor be categorized into the three types of noise-sensitive land uses (see Table 4.6-2)

Noise Impact Criteria

The FTA noise impact criteria are founded on well-documented research on community reaction to noise and are based on change in noise exposure using a sliding scale. Although higher levels of transit noise are allowed in neighborhoods with high levels of existing noise, smaller increases in total noise exposure are allowed with increasing levels of existing noise.

The Day-Night Sound Level (Ldn) is used to characterize noise exposure for residential areas (Category 2). For other noise sensitive land uses, such as parks and school buildings (Categories 1 and 3), the maximum 1-hour "equivalent" sound level (Leq) during the facility's operating period is used (see Section 4.6.1.1).

The relationship between impact assessment and the three impact categories is as follows. There are two levels of impact (severe and moderate) included in the FTA criteria, as summarized below:

- **No Impact**: If the project noise exposure is less than the No Impact criteria, no commuter rail impacts are predicted.
- **Moderate Impact**: In this range of noise impact, the change in the cumulative noise level is noticeable to most people but may not be sufficient to cause strong, adverse reactions from the community. In this transitional area, other project-specific factors must be considered to determine the magnitude of the impact and the need for mitigation. These factors include the existing noise level, the predicted level of increase over existing noise levels, the types and numbers of noise-sensitive land uses affected, the noise sensitivity of the properties, the effectiveness of the mitigation measures, community views, and the cost of mitigating noise to more acceptable levels. Moderate noise impact means that commuter rail service is predicted to increase noise exposures at sensitive land uses adjacent to the track.
- **Severe Impact**: Project-generated noise in the severe impact range can be expected to cause a significant percentage of people to be highly annoyed by the new noise and represents the most compelling need for mitigation. Noise mitigation will normally be specified for severe impact areas unless there are truly extenuating circumstances that prevent it. Severe impact means that commuter rail service is predicted to substantially increase noise exposures at sensitive land uses adjacent to the track.

The noise impact criteria are represented by the curves in Figure 4.6-2, also shown in *Transit Noise and Vibration Impact Assessment.*[5] In addition to graphic curves, the noise impact criteria can also be quantified through the use of mathematical equations included in Appendix B.3 of *Transit Noise and Vibration Impact Assessment*.[6] These equations reflect the curves shown in Figure 4.6-2, thus enabling the use of spreadsheets to facilitate the analysis of many sites. As described in *Transit Noise and Vibration Impact Assessment*,[7] the noise impact criteria are based on a comparison of the existing outdoor noise levels and the future outdoor noise levels from a proposed project. They incorporate both absolute criteria, which consider activity interference caused by the transit project alone, and relative

[5] Ibid.
[6] Ibid.
[7] Ibid.

criteria, which consider annoyance caused by the change in the noise environment caused by the transit project.

The horizontal axis of the graph in Figure 4.6-2 is the existing noise exposure and the vertical axis shows the additional noise exposure from the transit project that would cause either moderate or severe impact. The scale on the left vertical axis applies to the more noise-sensitive land uses in Categories 1 and 2 as described earlier. The scale on the right vertical axis applies to Category 3 land uses, which are less noise-sensitive than Categories 1 and 2. The future noise exposure would be the combination of the existing noise exposure and the additional noise exposure caused by the transit project. Because sound levels represent energy, their values cannot be simply added and are combined logarithmically.

As described in *Transit Noise and Vibration Impact Assessment*,[8] the two curves in Figure 4.6-2 defining the FTA impact criteria allow increasing project noise levels as existing noise increases up to a point, beyond which impact is determined based on project noise alone. Below the lower curve in Figure 4.6-2, a proposed project is considered to have no noise impact since, on average, the introduction of the project will result in an insignificant increase in the number of people highly annoyed by the new noise. The curve defining the onset of noise impact stops increasing at 65 dB for Category 1 and 2 land use, a standard limit for an acceptable living environment defined by a number of federal agencies. Project noise above the upper curve is considered to cause Severe Impact since a significant percentage of people would be highly annoyed by the new noise. This curve flattens out at 75 dB for Category 1 and 2 land use, a level associated with an unacceptable living environment. As indicated by the right-hand scale on Figure 4.6-2, the project noise criteria are 5 dB higher for Category 3 land uses since these types of land use are considered to be slightly less sensitive to noise than the types of land use in Categories 1 and 2. Between the two curves the proposed project is judged to have Moderate Impact. Although the curves in Figure 4.6-2 are defined in terms of the project noise exposure and the existing noise exposure, it is the increase in the cumulative noise—when project noise is added to existing noise—that is the basis for the criteria.

To illustrate this point, Figure 4.6-3 shows the noise impact criteria for Category 1 and 2 land use in terms of the allowable increase in the cumulative noise exposure. The horizontal axis is the existing noise exposure and the vertical axis is the increase in cumulative noise level caused by the transit project. The measure of noise exposure is Ldn for residential areas and Leq for land uses that do not have nighttime noise sensitivity. Since Ldn and Leq are measures of total acoustic energy, *any* new noise source in a community would cause an increase, even if the new source level is less than the existing level. As shown in Figure 4.6-3, the criterion for Moderate Impact allows a noise exposure increase of 10 dBA if the existing noise exposure is 42 dBA or less but only a 1 dBA increase when the existing noise exposure is 70 dBA.

The procedure for assessing impact is to determine the existing noise exposure and the predicted project noise exposure at a given site, in terms of either Ldn or Leq(h) as appropriate, and to plot these levels on Figure 4.6-2. The location of the plotted point in the three impact ranges is an indication of the magnitude of the impact.

[8] Ibid.

Figure 4.6-2 FTA Noise Impact Criteria

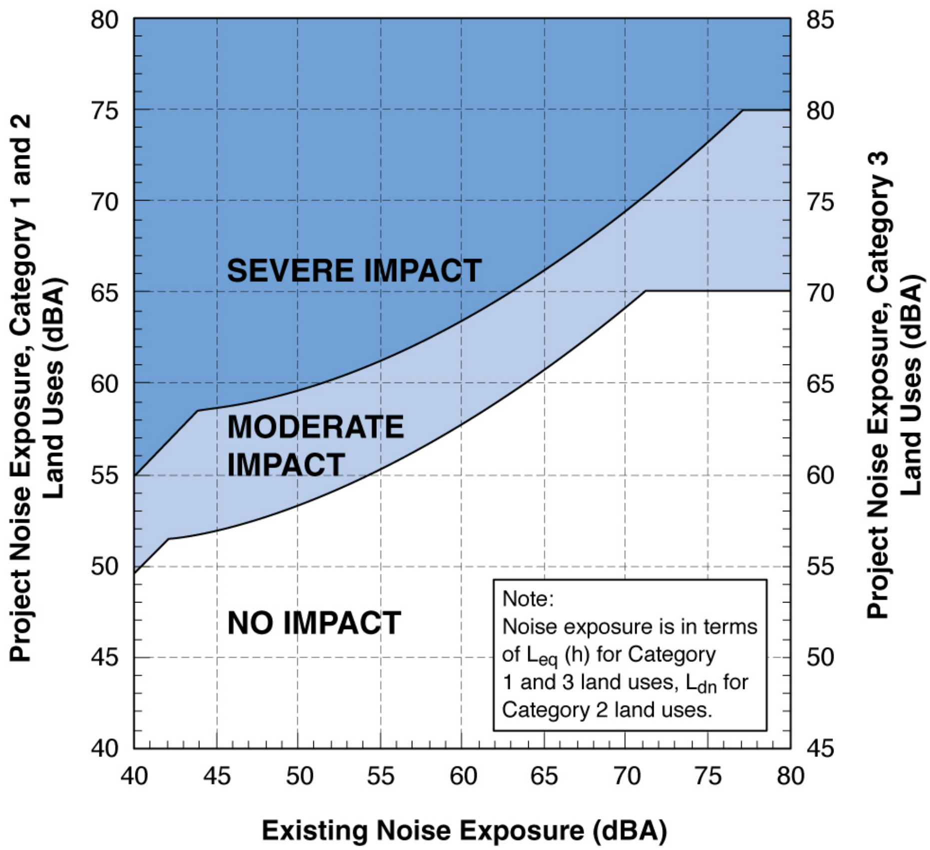

Figure 4.6-3 Increase in Cumulative Noise Levels Allowed by FTA Criteria

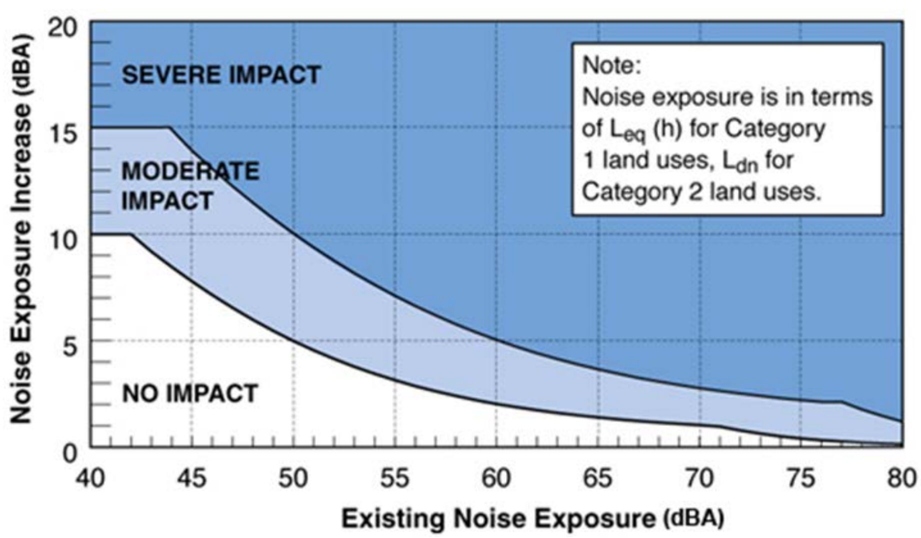

As described in *Transit Noise and Vibration Impact Assessment*,[9] when the existing level of ambient noise increases, the allowable level of transit noise also increases, but the total amount that community noise exposure is allowed to increase is reduced. A project noise exposure that is less than the existing noise exposure can thus still result in an impact, especially where existing noise exposure is already high.

In certain cases, according to *Transit Noise and Vibration Impact Assessment*,[10] only the cumulative form of the noise criteria as shown in Figure 4.6-3 should be used. These cases involve projects where changes are proposed to an existing transit system, as opposed to a new project in an area previously without transit. Such changes might include operations of a new type of vehicle, modifications of track alignments within existing transit corridors (such as moving the existing commuter rail lines for the South Coast Rail project, or changes in facilities that dominate existing noise levels. In these cases, the existing noise sources change as a result of the project, and so it is not possible to define project noise separately from existing noise.

Another condition cited in *Transit Noise and Vibration Impact Assessment*[11] includes a commuter rail corridor where the existing noise along the alignment is dominated by diesel locomotive-hauled trains and where the project involves replacement of some of the diesel-powered locomotives with electric trains operating at increased frequency of service and higher speeds on the same tracks. In this case, the existing noise can be determined and a new future noise can be calculated, but it is not possible to describe what constitutes the “project noise.” For example, if the existing noise dominated by trains was measured to be an Ldn of 63 dBA at a particular location, and the new combination of diesel and electric trains is projected to be an Ldn of 65 dBA, the change in the noise exposure caused by the project would be 2 dB. Referring to Figure 4.6-3, a 2 dB increase with an existing noise exposure of 63 dBA would be rated as a Moderate Impact. Normally the project noise is added to the existing noise to come up with a new cumulative noise, but in this case, the existing noise was dominated by a source that changed because of the project, so it would be incorrect to add the project noise to the existing noise.

A similar example would be a rail corridor where a track is added and grade crossings are closed, potentially resulting in a change in train location and horn operation. In this case the “project noise” results from moving some trains closer to some receivers, away from others, and elimination of horns, and the *change* in noise level is more readily determined than the noise from the actual project elements.

Noise generated by train operations depends on the type and number of locomotives and rail cars, the type of rail and track structure, the speed of the train, and the condition of rail and train wheels. The noise assessment is based on the following assumptions, which have a direct effect on the noise exposure resulting from the rail operations:

- Each train contains either one diesel or electric locomotive and eight coaches.
- The train speeds were based on the proposed track charts for each alternative. Diesel and electric locomotives were assumed to have a maximum speed of 70 and 100 mph, respectively.

[9] Ibid.
[10] Ibid.
[11] Ibid.

- The track is continuously welded (without joints that create impact noise) and is secured to concrete ties mounted on rock ballast.
- The train wheels are true (without flat spots) and the rail is smooth (without corrugations).
- Train warning horns will be used on a routine basis at all grade-crossings.

Future noise levels from the commuter trains are projected based on the existing measured noise levels at sensitive locations and changes to the alignment. Since future noise levels are based on existing noise levels, where appropriate, the projections include all operations from MBTA commuter trains, Amtrak trains, and freight rail activity. With this modeling approach, the projections include the contributions from several factors, such as train speed, presence of special trackwork or other site-specific conditions.

The existing and future commuter train noise levels depend on different sound propagation conditions caused by changes to the commuter rail alignment and modification to any special trackwork. The relative contributions of noise from trains on both tracks and from locomotives versus rail cars are included in this modeling. Future noise levels from the proposed South Coast Rail trains are based on reference noise levels (discussed below), site-specific conditions such as the terrain, intervening objects such as building rows, and operational plans including the number of cars in a train, speed, and headways.

Commuter Rail Operations

Noise-sensitive locations along the proposed commuter rail corridors were identified from MassGIS, aerial photography, and field survey. The majority of the noise-sensitive buildings within 1,000 feet of the rail corridor are residences (Land Use Category 2). Numerous schools, places of worship, and libraries (Land Use Category 3) were identified near the rail line. No amphitheaters, concert pavilions, or National Historic Landmarks with significant outdoor use (Land Use Category 1) were identified within 1,000 feet of the rail corridor.

Existing noise exposure at sensitive receptors along the proposed commuter rail corridor varies from 45 to 70 Ldn for the No-Build Alternative. The corridor passes through urban, suburban, and rural areas that have existing noise exposures that range from quiet to moderately noisy. These existing noise exposures are dominated by noise from nearby roadways. Existing noise exposures above 60 Ldn generally result from traffic volume adjacent to the rail corridor and/or from current train activity on the rail corridor. Both occur at locations that are within 150 feet of the existing track.

Impact distances from the rail line were calculated based upon the existing sound levels, train generated sound levels, and distances to noise impacts based upon FTA's noise impact criteria.[12] The FTA's noise impact criteria (see Figures 4.6-2 and 4.6-3) establish the noise impact sound levels (thresholds) based upon the existing sound levels for each receptor location. The noise analysis calculates the distances to the noise impact sound levels based upon the train activity at the receptor locations. The MassGIS mapping identifies the number of receptor locations within the distances of noise impacts. These calculations were conducted for both moderate and severe noise impacts. Table 4.6-4 summarizes the calculated noise impact distances for various existing sound levels.

[12] Federal Transit Administration, Transit Noise and Vibration Impact Assessment, figures 3-1 and 3-2: "Noise Levels Defining Impact for Transit Projects", FTA-VA-90-1003-06, May 2006.

Table 4.6-4 Noise Impact Distances (Feet), by Existing Noise Level (dBA)

Existing Sound Level (Ldn)	Distance to Impact Level (Feet) Severe Closer than (ft.)	Moderate Between (ft.)	No Impact farther than (ft.)
50-54	225	225-450	450
55-59	120	120-400	400
60	115	115-225	225
61	100	100-200	200
62	100	100-200	200
63	75	75-175	175
64	75	75-175	175
65	65	65-150	150
66	55	55-135	135
67	55	55-135	135
68	50	50-115	115
69	45	45-100	100
70	45	45-100	100

Horn Issues and Considerations

In 1996, the U.S. Congress passed the Swift Act, which requires that railroads sound whistles at all grade crossings. The Act provided an exception for grade crossings that are equipped with supplemental safety measures, such as extended barriers, medians, one-way streets, or four quadrant gates. For analysis purposes, it was assumed that the horns will be sounded one-quarter mile prior to all public grade crossings for each of the rail alternatives. This horn is required as a safety measure by the Federal Railroad Administration, Department of Transportation.[13]

4.6.3.3 Impacts of Alternatives by Element

No-Build (Enhanced Bus) Alternative

The No-Build Alternative would not include any change in existing train activity but would include an enhancement of the current bus service along existing roads and highways. It was assumed that the limited increase in bus service would occur along major roadways (I-93 and Route 24) and commuter parking areas. The low volumes of increased buses on these roadways would have a minimal effect on the sound levels within the study area.

The FTA Guidelines require that noise impacts are based on the comparison between existing sound levels and future build sound levels. The assumption that the 2030 No-Build sound levels are equal to the existing sound levels provides a uniform and conservative basis for comparison to the Build Alternatives. Furthermore, sound levels in the area that measurements were conducted are not anticipated to change significantly (1 to 3 dBA) over the next 20 years. Therefore it is conservative to assume that the 2030 No-Build sound levels are equal to the existing sound levels and this assumption does not affect the determination of potential noise impacts. Therefore the existing (2009) sound levels

[13] Federal Railroad Administration, Department of Transportation13, Title 49, Chapter II: PART 222—Use of Locomotive Horns at Public Highway Rail Grade Crossings.

were assumed for the future (2030) No-Build Alternative. Table 4.6-5 presents a summary of the sound levels for the No-Build (Enhanced Bus) Alternative.

Southern Triangle Study Area (Common to All Rail Alternatives)

Portions of the rail elements within the southern part of the South Coast Rail study area are common to all the rail alternatives. These rail elements form a triangular shape between the Fall River Secondary and the New Bedford Main Line, and are therefore referred to as the Southern Triangle. The Fall River Secondary extends from Myricks Junction to Fall River. The New Bedford Main Line extends from Weir Junction to New Bedford. The following sections describe the environmental consequences related to the noise impacts that may result from the South Coast Rail project. The northern elements of the South Coast Rail study area are encompassed by the other rail Build Alternatives described in subsequent sections.

Fall River Secondary Rail Segment

The existing Fall River Secondary freight track would be upgraded to Federal Rail Administration (FRA) Class 5[14] for the South Coast Rail project. Public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. The existing freight service using the Fall River Secondary is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would need to be constructed along the length of the line and two new traction power facilities would need to be constructed for the electric alternatives. Two new stations would be constructed in Fall River (Battleship Cove and Fall River Depot) and one new station would be constructed in Freetown (Freetown). One new layover facility would be constructed in Fall River, at the Weaver's Cove East site. Potential noise impacts to land uses resulting from constructing the new stations and layover facilities along the Fall River Secondary are considered in the Stations and Layover Facilities sections, respectively.

As shown in Table 4.6-6, electric train operations for the Fall River Secondary would result in 466 moderate and 135 severe impacts to residential receptors. The majority of these would occur in Fall River, in the Cory and Durfee Street neighborhoods. The diesel operations would have greater impacts than electric commuter rail along the Fall River Secondary, with 570 moderate and 181 severe impacts (Table 4.6-7). Train horns along this corridor would add 98 moderate and 164 severe impacts (Table 4.6-8). Mapping of the noise impacts associated with the Fall River Secondary segment is provided as follows:

- Diesel alternatives train pass-by noise impact areas and horn noise impacts for both diesel and electric alternatives: Figures 4.6-4a through 4.6-4c.
- Updated train pass-by noise impacts for electric alternatives: Figures 4.6-4a through 4.6-4c.

New Bedford Main Line Rail Segment

The existing New Bedford Main Line freight track would be upgraded to FRA Class 5 for the South Coast Rail project. Public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. The existing freight service using the New Bedford Main Line is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would need to be constructed along the length of the line, and four or five traction power facilities (depending upon the alternative selected) would need to be constructed for the electric alternatives. Two new train stations would be constructed in New Bedford (Whale's Tooth and King's Highway), and one new train station would be constructed in Taunton (Taunton Depot). One new layover facility would be constructed at the Wamsutta site. Potential direct impacts to land uses resulting from the constructing the new stations and layover facility along the New Bedford Main Line are considered in the Stations and Layover Facilities sections, respectively.

As shown in Table 4.6-9, electric train operations for the New Bedford Main Line segment would result in 236 moderate and 47 severe impacts to residential receptors. The majority of these would occur in Taunton and New Bedford, in the Plain Street, Welby Road, and Worcester Street neighborhoods. The diesel operations would have lower impacts, with 185 moderate and 35 severe impacts (Table 4.6-10). Train horns along this segment would add 93 moderate and 76 severe impacts (Table 4.6-11).

Mapping of the noise impacts associated with the New Bedford Mainline is provided as follows:

- Diesel alternatives train pass-by noise impact areas and horn noise impacts for both diesel and electric alternatives: Figures 4.6-5a through 4.6-5e.
- Updated train pass-by noise impacts for electric alternatives: Figures 4.6-5a through 4.6-5e.

Stoughton Electric Alternative

The Stoughton Electric Alternative would comprise a portion of the Northeast Corridor, the entire Stoughton line, and the Southern Triangle elements. This alternative would use the Northeast Corridor from South Station to Canton Junction. From Canton Junction, the existing Stoughton Line would be used to the existing Stoughton Station. From there, commuter rail service would be extended, reconstructing a railroad on an out-of-service railroad bed, south through Raynham Junction to Weir Junction in Taunton. This alignment joins the New Bedford Main Line at Weir Junction, the northern end of the Southern Triangle. This evaluation focuses on the existing and extended Stoughton Line segment.

The existing Stoughton Line commuter rail track from Canton Junction to Stoughton Station would be upgraded to FRA Class 5 for the Stoughton Electric Alternative. New track would be placed on the out-of-service railroad bed from Stoughton Station south to Weir Junction. The existing public at-grade road/railroad crossings would be reconfigured and/or improved to meet current safety standards. The improved track and at-grade road/railroad crossings would also reduce sound levels generated by train activities.

As shown in Table 4.6-12 and Figures 4.6-6h-l, electric train operations for the Stoughton Line segment would result in 404 moderate and 159 severe impacts to residential receptors. The majority of these would occur in Easton and Raynham, in the Elm Street (Easton), Bridge Street, and Elm Street (Raynham) neighborhoods. Train horns along this segment would add 437 moderate and 457 severe impacts (see below).

Stoughton Diesel Alternative

The Stoughton Diesel Alternative alignment comprises same components as the Stoughton Electric Alternative with the exception of the locomotive power source. Due to lower operating speeds of diesel trains (and thus lower noise levels) the diesel operations would have slightly lower noise impacts than the electric operations, with 330 moderate and 128 severe impacts (See Table 4.6-13 and Figures 4.7h-l). Table 4.6-14 summarizes the horn noise impacts along the Stoughton Line for the diesel and electric alternatives.

Whittenton Electric Alternative

The Whittenton Electric Alternative is a modification of the Stoughton Electric Alternative alignment described previously. At Raynham Junction, the route would divert to the southwest, following the out-of-service Whittenton Branch. This alignment would connect with the Attleboro Secondary at Whittenton Junction in Taunton, and then continue on toward the southeast to connect with the New Bedford Main Line at Weir Junction. The southernmost portion of the Stoughton Line (from Raynham Junction to Weir Junction) would not be used under this alternative. This evaluation focuses on the Whittenton Branch and Stoughton segment components; other components of this alternative (Southern Triangle Fall River Secondary and Southern Triangle New Bedford Main Line) are described in the section on the Southern Triangle study area.

As shown in Table 4.6-15 and Table 4.6-16 and Figures 4.6-7a-b, electric train operations would result in 171 moderate and 35 severe impacts to residential receptors for the Whittenton segment and 359 moderate and 164 severe impacts to residential receptors for the Stoughton segment. Train horns along the Whittenton segment would add 460 moderate and 708 severe impacts with an additional 368 moderate and 374 severe impacts along the Stoughton segment (see Tables 4.6-19 and 4.6-20).

Note: This table represents the Whittenton Branch and the Attleboro Secondary from Whittenton Junction to Weir Junction.

Whittenton Diesel Alternative

The Whittenton Diesel Alternative is identical to the Whittenton Electric Alternative with the exception of the locomotive power source. As shown in Tables 4.6-17 and 4.6-18, diesel operations would result in 194 moderate and 42 severe impacts along the Whittenton segment and 279 moderate and 109 severe impacts along the Stoughton segment. As mentioned in the previous section, train horns along the Whittenton segment would add 460 moderate and 708 severe impacts with an additional 368 moderate and 374 severe impacts along the Stoughton segment (See Tables 4.6-19 and 4.6-20).

Note: This table represents the Whittenton Branch and the Attleboro Secondary from Whittenton Junction to Weir Junction

Stations

Noise at the proposed South Coast Rail train stations would be dominated by trains approaching and departing the stations. The other minor noise sources include automobiles, which are associated with the patron arrivals and departures, bus idling in the bus loading zones, and P.A. systems in the platform area (if any are constructed) are not expected to contribute to the overall sound levels and impacts. Trains would idle at the train stations for a brief period to discharge and pick-up passengers. As a result, the dominant noise source around the train stations would be from approaching and departing trains. The sound level results and impacts of receptor locations near train stations are summarized in Tables 4.6-6 through 4.6-20.

For the Stoughton Electric Alternative, the impact analysis results take into account the relocation of the Stoughton Station as described in Chapter 3. Impact analysis results for the Stoughton Diesel Alternative have not been updated since the DEIS/DEIR and thus reflect the original Stoughton Station location. Similarly, the noise impact analyses for the Whittenton Diesel and Electric Alternatives do not take into account the relocation of the Stoughton Station or the change in the Downtown Taunton Station location to Dana Street. However, given that noise in the vicinity of stations is dominated by train

operations, not the stations themselves, the station location changes would not substantially change noise impacts from those presented in the DEIS/DEIR for the purposes of comparing alternatives.

Layover Facilities

Noise at the proposed South Coast Rail layover facilities would be dominated by trains idling diesel locomotives (under the diesel alternatives only). Diesel trains that remain at the layover facilities for 1 hour or longer would be shut down and attached to electrical power, as needed. The other minor noise sources on site are not expected to contribute to the overall sound levels and impacts. Distances to moderate and severe impact at the layover facilities were calculated based on the Source Reference Level of 109 dBA at 50 feet from the center of the site for layover tracks, based on Table 5-5 of *Transit*

Noise and Vibration Impact Assessment.[15] This analysis revealed one moderate impact at the proposed Weaver's Cove facility. The existing sound levels, the project sound levels, and the number of impacts are shown in Table 4.6-21 and Figures 4.6-4b and 4.6-5e.

Table 4.6-21 Layover Facilities Sound Levels and Impacts

Layovers Location	Noise Exposure at 50 feet (Ldn)	Existing Noise Exposure (Ldn)	Moderate Impact Ldn	Moderate Impact Number of Impacts	Severe Impact Ldn	Severe Impact Number of Impacts
Fall River - Weaver's Cove East	79.8	55	55.3	1	61.2	0
New Bedford - Wamsutta Site	79.8	60	57.8	0	63.4	0

Assumptions: A Source Reference Level of 109 dBA at 50 feet from the center of the site for layover tracks was used based on Table 5-5 of Transit Noise and Vibration Impact Assessment.
All facilities are assumed to have one train idling per hour (day and night).

4.6.3.4 Temporary Construction-Period Impacts and Mitigation

Temporary noise impacts could result from construction activities associated with utility relocation, grading, excavation, track work and installation of systems components. Such impacts may occur in residential areas and at other noise-sensitive land use located within several hundred feet of the alignment. The potential for noise impact would be greatest at locations near pile driving operations for bridges and other structures, and at locations close to any nighttime construction activities.

Track Improvements

The South Coast Rail project may create noise impacts as a result of track and bridge reconstruction activities. Construction activities would increase sound levels in adjacent areas; however, these sound level increases would be temporary and would move with construction activities. The particular types of construction equipment or activities are not defined at this stage of the design. Therefore, construction impacts cannot be quantitatively assessed at this time.

Since rail replacement activities, which include grading, ballast, and rail construction, would continuously move along the corridor, noise from these activities would only occur for several weeks at any one location. Bridge and grade crossing reconstruction activities would occur for a slightly longer duration, since these activities require more time. None of the noise impacts associated with track improvements would be permanent.

Station Construction

Station construction activities may increase noise exposures in adjacent areas during some phases of the construction. However, these increases would be temporary. Since particular construction equipment and activities are not defined at this stage of design, construction impacts cannot be quantitatively assessed at this time.

MassDOT has indicated that every reasonable attempt would be made to minimize construction noise impacts. Construction noise control is accomplished by the use of quiet equipment and procedures. Noise guidelines would be incorporated into construction documents and would conform to local, state,

[15] *Transit Noise and Vibration Impact Assessment*, Federal Transit Administration, May 2006

and federal statutes. Specific noise control measures would be reviewed during detailed engineering design and be negotiated as part of the construction permitting process. Noise specifications would be enforced through a program of field inspection and compliance review.

Mitigation for Construction-Period Impacts

MassDOT has indicated that every reasonable attempt would be made to minimize construction noise impacts. Construction noise control is accomplished by the use of quiet equipment with enclosed engines and/or high-performance mufflers and quieting procedures such as locating stationary construction equipment as far as possible from noise-sensitive sites. Noise guidelines would be incorporated into the construction documents and conform with local, state, and federal statutes. Specific noise control measures would be reviewed during detailed engineering design and be negotiated as part of the construction permitting process. Noise specifications would be enforced through a program of field inspection and compliance review.

Most of the track and bridge reconstruction would occur during the normal workday. Under special circumstances, where road or rail traffic interruptions have to be minimized, night work may occur. During these conditions, unusually noisy activities would be scheduled during daytime hours to minimize noise impacts to residential areas during periods of rest and sleep.

The station construction work would occur during the normal workday. Under special circumstances, when night work may occur, unusually noisy activities would be scheduled during daytime hours to minimize noise impacts to residential areas during periods of rest and sleep.

4.6.3.5 Summary of Impacts by Alternative

Table 4.6-22 summarizes the total number of moderate and severe noise impacts by alternative for the operations of the rail line. All of the severe noise impact locations were evaluated for noise mitigation measures.

The Stoughton Electric alternative (Stoughton, Southern Triangle - Fall River, and Southern Triangle - New Bedford segments) would result in 1,106 moderate and 341 severe impacts to residential receptors. The diesel operations would have similar impacts, with 1,085 moderate and 344 severe impacts.

The Whittenton Electric alternative (Stoughton partial, Whittenton, Southern Triangle - Fall River, and Southern Triangle - New Bedford segments) would result in 1,232 moderate and 381 severe impacts to residential receptors. The diesel operations would have lower impacts, with 1,228 moderate and 367 severe impacts.

Severe noise impacts typically result from the close proximity to locomotive and rail car noise and from locomotive warning horns, which must be sounded one-quarter mile prior all public grade crossings. Severe noise impacts result from Ldn noise exposure increases of 2 to 6 dBA (depending on existing). It should be noted that the majority of train horn impacts would occur at the same locations where rail operation impacts would occur. The train horn, however, is a uniquely different noise than the operations and was evaluated separately. A summary of these results can be found in Table 4.6-23. All of the severe noise impact locations were evaluated for noise mitigation measures.

Table 4.6-22 Summary of Projected Noise Impacts for South Coast Rail Alternatives

Alternative	Electric Alternative Moderate Impacts	Electric Alternative Severe Impacts	Electric Alternative Total	Diesel Alternative Moderate Impacts	Diesel Alternative Severe Impacts	Diesel Alternative Total

Total	**1,019**	**1,322**	**2,341**

* Excludes the portion of the Stoughton line that is bypassed by the Whittenton Alternative (south of Raynham Junction).

Train horns along the Stoughton Alternative would have 628 moderate and 689 severe impacts. The Whittenton Electric Alternative would result in the train horns producing 1,019 moderate and

1,322 severe impacts. The Whittenton alternative results in the highest railroad grade crossing noise impacts.

4.6.3.6 Mitigation

Overview of MBTA Train Pass-by Noise Mitigation Policy

The need for noise mitigation in a specific location is determined based on the magnitude of the impacts and consideration of other factors such as feasibility, cost-effectiveness, and community views. The Corps does not have mitigation evaluation criteria for commuter rail projects and therefore relies on the guidance of the federal agency with special expertise in this area, the FTA. The FTA guidance requires consideration of mitigation for severe impacts and outlines the available mitigation options. FTA allows transit providers to develop local agency-specific noise mitigation policies detailing the analysis process and criteria for their projects. MBTA has developed a noise mitigation policy consistent with the FTA guidance, the details of which are described below.

The MBTA is committed to providing noise mitigation to the locations that meet or exceed the Severe Noise Impact Level. Noise mitigation measures would be provided to the extent that it is reasonably cost-effective. Where noise levels are projected to occur above the Severe Noise Impact Level, the MBTA may consider a reduced level of noise mitigation that is proportional to the level of impact over the threshold level and which, again is reasonably cost-effective.

The Severe Noise Impact Level is reached when the projected noise level from the project significantly exceeds the ambient noise level. These noise impacts are measured at the outside of the building, at the corner or wall closest to the tracks, at 5 feet above the ground. Where sensitive land uses such as residences (as defined in the FTA guidelines) are impacted at the Severe Noise Impact Level, the MBTA would provide noise barriers or other noise measures designed to reduce the noise impact, if cost-effective. Such measures would be considered cost-effective by the MBTA if the total cost of the wall or other measure is less than $30,000 per dwelling unit, and the wall is found to be effective in reducing noise levels below the impact threshold.

The MBTA would initially evaluate the severe impact locations to determine if a noise barrier can be provided. Where noise barriers are not cost-effective by the above standard, or where noise barriers cannot provide a sufficient level of noise reduction, the MBTA would consider providing funding for building noise mitigation. The cost-effectiveness limit for building noise mitigation would be $5,000 per dwelling unit per decibel of noise impact projected above the Severe Noise Impact Level (not to exceed $30,000 total). Thus, for example, if a dwelling unit is expected to have noise impacts 3 decibels (using the Ldn metric) above the Severe Noise Impact Level, the building noise mitigation measures would be funded not to exceed $15,000 in cost for that dwelling unit.

The $5,000 per dwelling unit per decibel figure was calculated by dividing the $30,000 total cost-effectiveness limit by 6 decibels, which is the typical difference between the “impact” threshold and “severe” impact level according to the FTA Manual.

The owners of properties that are affected by noise above the Severe Noise Impact Level, and who may be eligible for building noise mitigation under these guidelines, would be consulted during the design phase of the project. The MBTA would permit these homeowners to identify preferred building noise mitigation measures for their property from a list of potential measures that would be provided by the MBTA. The list would include measures such as window replacement or sound insulation in the house,

provided that the MBTA noise consultants determine that such measures are reasonably effective as noise reducing techniques in the context of the specific location involved. Where a homeowner elects to have work done on his or her property, he or she would be responsible for selecting the contractor and obtaining necessary permits, and the MBTA would pay the contractors bills from its own funds (thus avoiding the need for the homeowner to come "up front" with cash resources) up to the specified dollar limit for the particular location and noise condition involved. The list of eligible measures may also include reduced-height noise barriers or similar measures, subject to the cost-effectiveness limit, in cases where a homeowner judges that notwithstanding the lack of effectiveness of the reduced height structure, the homeowner prefers the psychological "space" created by the structure over the actual noise reduction achieved.

Similarly, homeowners in this category may elect, singly or in concert with other similarly affected homeowners, to install measures that may not reduce exterior noise levels, or may not be fully effective in reducing interior noise levels. Some of these mitigation measures, such as air conditioning (to allow residents to keep their windows closed when sleeping) may in fact increase both exterior and interior noise levels. As a result, however, there can be no guarantee that any particular level of noise reduction would be achieved based upon measures selected by the homeowner.

The MBTA's role would be limited to evaluating potential noise mitigation and paying for the installation of appropriate noise mitigation treatments. The homeowner would obtain guarantees for equipment or for workmanship from their contractors, and future replacement or maintenance would be the responsibility of the homeowner. Homeowners would be expected to enter into letter agreements with the MBTA acknowledging this understanding as a condition of proceeding with the installation of noise mitigation measures under these Guidelines.

Stoughton Electric Alternative Proposed Noise Mitigation Plan

This section presents a summary of the proposed noise mitigation measures for the severe noise impacts associated with the Stoughton Electric Alternative. Subsequent to the DEIS/DEIR, MassDOT conducted a noise impact analysis that re-evaluated the noise impacts associated with the changes in rail operations of the Stoughton Electric Alternative and identified severe noise impact locations. MassDOT's Noise Mitigation Plan evaluated the noise mitigation measures for these severe noise impact locations. The severe noise impact locations were evaluated to identify the potential noise mitigation measures, either noise barriers or building insulation in accordance with the MBTA noise mitigation policy described above. The location of the noise impact locations and proposed noise barriers are presented in Figures 4.6-4d through 4.6-4h; 4.6-5f through 4.6-5i; and 4.6-6a through 4.6-6g . A listing of the severe noise impact locations and their proposed noise mitigation measures are presented in Appendix 4.6-C. The following is a summary of the proposed noise mitigation measures by municipality.

Stoughton

The noise analysis identified 21 severely impacted noise sensitive receivers (Figures 4.6-6a-c). An evaluation of constructing a noise barrier indicated that due to the low density of these receptors, a noise barrier was not cost-effective for this area. Building insulation is the most cost-effective noise mitigation for the severely impacted noise sensitive receivers in Stoughton due to the distance between those noise impact locations.

Easton

The noise analysis identified 104 severely impacted noise sensitive receivers. The analysis determined that a noise barrier is the most cost-effective mitigation measure for the 23 severely impacted noise sensitive receivers located in the Center Street area (Figures 4.6-6b and 4.6-6d). The proposed noise barrier would be located parallel to Center Street and extend approximately from Main Street to Bridge Street. A noise barrier is also cost-effective for the 25 severe noise impacted locations located on Baldwin Street (Figures 4.6-6b and 4.6-6d). The proposed noise barrier would be located parallel to Baldwin Street and extend approximately from Bridge Street to Parker Terrace. Building insulation is the most cost-effective noise mitigation for the remainder of severely impacted noise sensitive receivers in Easton due to the distance between those noise impact locations.

Raynham

The noise analysis identified 23 severely impacted noise sensitive receivers (Figure 4.6-6f). Noise barriers are not cost-effective for the severe noise impact locations in Raynham due to the location and distance between the receivers. Building insulation is the most cost-effective noise mitigation for all severely impacted noise sensitive receivers in Raynham.

Taunton

The noise analysis identified 23 severely impacted noise sensitive receivers (Figures 4.6-5f and 4.6-6g). Noise barriers are not cost-effective for the severe noise impact locations in Taunton due to the location and distance between the receivers. Building insulation is the most cost effective noise mitigation for all severely impacted noise sensitive receivers in Taunton.

Berkley

The noise analysis identified 14 severely impacted noise sensitive receivers (Figures 4.6-4d and 4.6-5f). Noise barriers are not cost-effective for the severe noise impact locations in Berkley due to the location and distance between the receivers. Building insulation is the most cost-effective noise mitigation for all severely impacted noise sensitive receivers in Berkley.

Lakeville

The noise analysis identified 8 severely impacted noise sensitive receivers (Figures 4.6-5f and 4.6-5g). Noise barriers are not cost-effective for the severe noise impact locations in Lakeville due to the location and distance between the receivers. Building insulation is the most cost-effective noise mitigation for all severely impacted noise sensitive receivers in Lakeville.

Freetown

The noise analysis identified 25 severely impacted noise sensitive receivers (Figures 4.6-5g, 4.6-5h, and 4.6-4d). Noise barriers are not cost-effective for the severe noise impact locations in Freetown due to the location and distance between the receivers. Building insulation is the most cost-effective noise mitigation for all severely impacted noise sensitive receivers in Freetown.

New Bedford

The noise analysis identified 12 severely impacted noise sensitive receivers (Figure 4.6-5i). Noise barriers are not cost-effective for the severe noise impact locations in New Bedford due to the location and distance between the receivers. Building insulation is the most cost-effective noise mitigation for all severely impacted noise sensitive receivers in New Bedford.

Fall River

The noise analysis identified 111 severely impacted noise sensitive receivers (Figures 4.6-4d through 4.6-4h). The analysis determined that a noise barrier is the most cost-effective mitigation for the 16 severely impacted noise sensitive receivers located on the west side of the track in the Murray Street area (Figures 4.6-4f and 4.6-4g). The proposed noise barrier would extend approximately from Brightman Street to Cory Street. A noise barrier is also cost effective for the 14 severely impacted noise sensitive receivers located on the east side of the track in the Almy Street area (Figures 4.6-4f and 4.6-4g). The proposed noise barrier would extend approximately from Cory Street to President Avenue. Building insulation is the most cost-effective noise mitigation for the remainder of severely impacted noise sensitive receivers in Fall River.

Summary – Mitigation Commitments

The noise analysis identified four severely impacted noise sensitive areas that met MBTA's policy for a noise barrier. The noise analysis showed that a noise barrier would be the most cost-effective mitigation measure at the following locations:

- Barrier #1. Center Street area from Main Street to Bridge Street in Easton. This barrier would be approximately 1,700 feet long and cost $510,000. 23 residences with severe impacts would benefit, resulting in a cost of $22,174 per benefited residence.
- Barrier #2. Baldwin Street area from Bridge Street to Parker Terrace in Easton. This barrier would be approximately 1,700 feet long and cost $510,000. 24 residences with severe impacts would benefit, resulting in a cost of $21,250 per benefited residence.
- Barrier #3. Murray Street area from Brightman Street to Cory Street in Fall River. This barrier would be approximately 1,000 feet long and cost $300,000. 15 residences with severe impacts would benefit, resulting in a cost of $20,000 per benefited residence.
- Barrier #4. Almy Street area from Cory Street to President Avenue in Fall River. This barrier would be approximately 1,100 feet long and cost $330,000. 14 residences with severe impacts would benefit, resulting in a cost of $23,571 per benefited residence.

In total, 5,500 linear feet of noise barriers costing $1.65 million are proposed for the Stoughton Electric Alternative. The design details of the proposed noise barriers would continue to be refined in the final design process.

For the remaining severely impacted sensitive receptor locations, building insulation is the most cost-effective noise mitigation for reducing the noise impact associated with the rail operations along the Stoughton Electric Alternative.

Noise Mitigation for Other Alternatives

A detailed Noise Mitigation Plan has not been developed for the Stoughton Diesel, Whittenton Electric or Whittenton Diesel Alternatives. However, these alternatives result in noise impacts in many of the same locations as the Stoughton Electric Alternative and therefore noise barriers similar to those described for the Stoughton Electric Alternative would likely be feasible. As with the Stoughton Electric Alternative, building insulation would be used to address severe impacts in locations where noise barriers are not cost effective.

Train Horn Noise Mitigation

An option for reducing train horn noise impacts under FRA regulations (49 CFR Parts 222 and 22) would be to establish “quiet zones” at grade crossings. In a quiet zone, train operators would sound horns only in emergency situations rather than as a standard operational procedure because of safety improvements made to the at-grade crossings. Establishing a quiet zone requires cooperative action among the municipalities along the rail right-of-way, freight railroads and appropriate federal, state and local agencies. The municipalities are key participants as they must initiate the request to establish the quiet zone through application to FRA. In addition, to meet safety criteria, improvements are required at grade crossings; these may include modifications to the streets, raised medians, warning lights, four-quadrant gates and other devices. The FRA regulation also authorizes the use of automated wayside horns at crossings with flashing lights and gates as a substitute for the train horn. While activated by the approach of trains, these devices are pole-mounted at the grade crossings, thereby limit the horn noise exposure area to the immediate vicinity of the grade crossing. Although the establishment of quiet zones or the use of wayside horns would be very effective noise mitigation measure (eliminating all or nearly all horn noise impacts), considerable design analysis and coordination efforts would be required to determine if these measures are feasible. For NEPA purposes, the establishment of quiet zones is the recommended noise mitigation measure for horn noise impacts. However, this mitigation measure is dependent on actions by local governments in conjunction with numerous other government agencies and cannot be implemented by MassDOT or the Corps.

Unavoidable Noise Impacts

After the proposed noise mitigation measures (noise walls or building noise insulation) have been finalized, noise impacts may still be present. Noise walls can provide a maximum of approximately 10 dBA noise reduction, and usually protect only the yards and ground level floors. Building noise insulation (soundproofing) can provide 10 to 15 dBA of additional exterior-to-interior noise reduction, but does not mitigate exterior noise and the building’s windows must remain closed to maintain effectiveness.

4.7 VIBRATION

4.7.1 Introduction

This chapter describes the vibration analysis methodology, vibration assessment criteria, existing vibration levels, vibration impacts and mitigation measures.

4.7.1.1 Resource Definition

Ground-borne vibration, in the context of transit, refers to movement of the ground caused by train movements and is usually the result of interactions between the steel wheels of the locomotives and rail cars and the rail surfaces. Examples of such interactions (and subsequent vibration) include train wheels over jointed rail and untrue railcar wheel with “flats.” Unlike noise, which travels through the air, transit vibration typically travels along the surface of the ground. Depending on the geologic properties of the surrounding ground and the type of building structure exposed to transit vibration, the vibration propagation path between the track and the structure may be more or less efficient. Buildings with a solid foundation set in bedrock are “coupled” more efficiently to the surrounding ground and experience higher vibration levels than those buildings located in sandy soil.

Vibration induced by vehicle passbys is generally discussed in terms of displacement, velocity, or acceleration. However, human responses and responses by buildings and other objects are more readily described with velocity. Therefore, the average velocity (called the root mean square (RMS) velocity) is used to assess impacts associated with the human response to vibration (e.g. annoyance). The RMS vibration velocity levels are expressed in inches per second (ips) or vibration velocity levels in decibels (VdB). Vibration levels are referenced to 1-micro inch per second (mips).

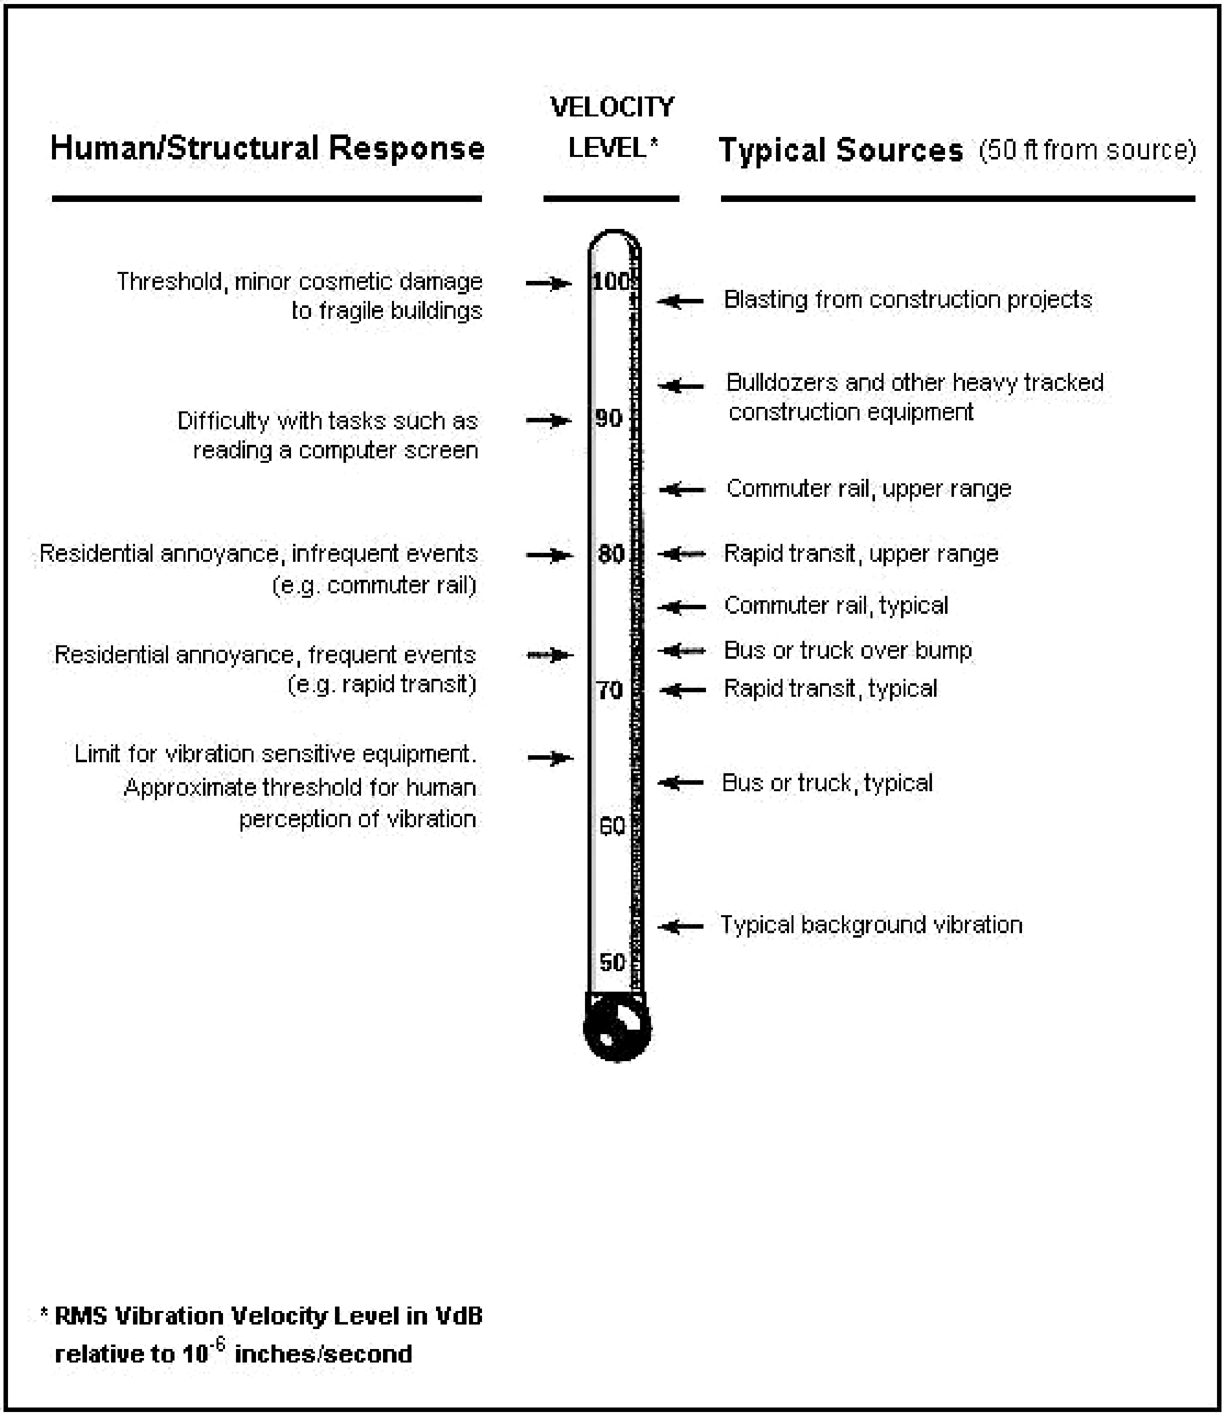
Typical ground-borne vibration levels from transit and other common sources are shown in Figure 4.7-1.

4.7.1.2 Regulatory Context

The vibration assessment for the South Coast Rail project was prepared in accordance with the FTA’s Transit Noise and Vibration Impact Assessment[1] guidance manual. The FTA guidance manual sets forth the basic concepts, methodology, and procedures for evaluating vibration levels from transit operations. There are no state or local regulations regarding vibration levels.

[1] FTA-VA-90-1003-06; May 2006.

Figure 4.7-1 Typical Ground-Borne Vibration Levels



4.7.2 Existing Conditions

Existing land uses in the study area are exposed to a variety of vibration sources ranging from trucks and vehicle passbys along local roadways, MBTA commuter rail train passbys along the existing rail corridors (Stoughton commuter rail line), and freight rail operations along the existing New Bedford and Fall River freight rail corridors.

A vibration measurement program was conducted in the study area to determine the existing vibration levels along the alignments of the various project alternatives. The vibration measurements were obtained using a CEL Model 593 meter with a PCB Model 393C accelerometer. The measured vibration levels consisted of a one-second interval time history of the train passby event reported in RMS velocity level in VdB relative to 1-micro inch per second.

Vibration was measured at four locations relevant to the Stoughton and Whittenton Alternatives in 1995 and 2008. These measured vibration levels are representative of the existing vibration levels along each of the proposed South Coast Rail alternatives. The vibration measurement locations and measured vibration levels are summarized in Table 4.7-1.

Actual vibration measurements were used to evaluate existing conditions because they provide a more accurate assessment of vibration along the South Coast Rail alternatives than would modeling based on generalized soils or geologic information. Some geologic conditions are associated with efficient propagation characteristics that result in higher than normal vibration levels. For example, shallow bedrock, less than 30 feet below the surface, is likely to have efficient propagation. Other factors that can be important are soil type and stiffness. In particular, stiff clay soils have been associated with efficient vibration propagation. Investigation of soil boring records can be used to estimate the depth to bedrock and the presence of problem soil conditions. Geological maps or subsurface borings may be used at a later stage in the project if more detailed analysis of ground propagation is needed for specific sensitive receptors.

Table 4.7-1 Vibration Measurement Locations and Measurement Results (VdB)

ID	Measurement Location	City/Town	Land Use	Distance (feet)	Train Operation	Train Speed (mph)	Measured Vibration Level (VdB)
	Southern Triangle – Common to All Build Alternatives						
1	Beechwood Road	Freetown	Residential	75	Freight	20	88
2	Chace Road	Freetown	Residential	100	Freight	20	85
	Stoughton Alternative/Whittenton Alternative						
8	Pine Street (Waterfall Hills Apartments)	Canton	Residential	80	Commuter	35	95
9	1508 Central Street	Stoughton	Residential	60	Commuter	20	86

Source: KM Chng Environmental Inc., 1995 and 2008.

4.7.2.1 Southern Triangle

In 1995, vibration measurements along the Southern Triangle were obtained in Freetown (location 1 – Beechwood Road and location 2 – Chace Road). The condition of the freight rail tracks in this section of the rail corridor constrained train speeds to approximately 20 mph. The measured vibration levels from

the freight rail operations ranged from 88 VdB at a distance of 75 feet at location 1, and 85 VdB at a distance of 100 feet at measurement location 2. The freight rail corridor consists of jointed track and rail cars with wheel flats, both of which contribute to higher vibration levels from freight operations. Since 1995, freight operations between New Bedford and Fall River have not changed. It was assumed therefore, that vibration along these corridors has not changed either. As a result, no new vibration measurements were obtained along these sections of the corridors during the 2008 vibration measurement data collection program.

Depending on the train speed, the condition of the vehicle wheels, and the ground propagation characteristics, the vibration levels at residences along the New Bedford and Fall River lines are expected to range from 85 to 95 VdB at a distance of 50 feet from the track, 78 to 88 VdB at a distance of 100 feet from the track, and 72 to 82 VdB at a distance of 200 feet from the track.

4.7.2.2 Stoughton/Whittenton Alternative

Vibration measurements were obtained along the Commuter Rail Stoughton Line as part of the 2008 measurement program. Vibration measurements were obtained at two locations, one in Canton (location 8 – Pine Street) and one near downtown Stoughton (location 9 – 1508 Central Street). As shown in Table 4.7-1, the measured vibration levels along this section of the Stoughton Line ranged from 86 VdB to 95 VdB at distances ranging from 60 to 80 feet from the tracks.

Vibration levels along the New Bedford Main Line (Weir Junction to Cotley Junction) are expected to range from 85 to 91 VdB at distances of 50 to 100 feet from the tracks. These vibration levels were not measured, but are expected to be similar to the freight rail vibration levels that were measured along the Southern Triangle. There are no train vibrations along the out-of-service segment of the corridor.

4.7.3 Analysis of Impacts and Mitigation

4.7.3.1 Introduction

This section addresses the vibration levels and potential impacts associated with the proposed commuter rail operations along the various corridor alignment alternatives. The remainder of this section describes the vibration analysis methodology, the assessment criteria, and the number and location of potential vibration impacts along each of the proposed alternative project corridors.

The Secretary's Certificate[2] required the DEIR to discuss consistency with applicable state and federal guidelines and regulations, and that the vibration impact assessment for the project alternatives identify impacted areas along the rail and bus routes and at the station sites. The Certificate further required the DEIR evaluate measures to avoid and minimize vibration impacts and include an assessment of impacts to wildlife.

The Secretary's Certificate on the DEIR, dated June 29, 2011, included the following requirements for the analysis of vibration.

[2] The Commonwealth of Massachusetts Executive Office of Energy and Environmental Affairs, Certificate of the Secretary of Energy and Environmental Affairs on the Environmental Notification Form, South Coast Rail Project (EEA# 14346), April 3, 2009.

- "The FEIR should compare the estimated vibration levels to existing conditions and describe the actual change that will be experienced. This additional information should be provided for residential impacts along the Stoughton route as well as for historic buildings."[3]

- "The FEIR should include a mitigation plan with clear and specific commitments to address vibration impacts and an explanation of the reduction in VdB levels expected."

This section evaluates vibration impacts to residential and other buildings. Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*, considers potential vibration impacts to wildlife.

4.7.3.2 Vibration Assessment Criteria

Table 4.7-2 presents FTA's vibration impact criteria for various land use categories, as well as the frequency of events. The criteria are related to ground-borne vibration causing human annoyance or interfering with the use of vibration-sensitive equipment (e.g., medical imagery equipment, audio/visual recording equipment, scientific sensing and measuring equipment). No buildings with vibration-sensitive special equipment (Category 1) were identified in the inventory of land uses in the project area. All sensitive receptors, such as residences and schools within the project area fall under Land Use Categories 2 and 3. The criteria for acceptable ground-borne vibration are expressed in terms of RMS velocity levels in VdB and are based on the maximum levels for a single event (L_{max}). In addition, vibration criteria have also been established for other specific buildings such as concert halls, recording studios, auditoriums and theaters that are also contained in Table 4.7-2.

Table 4.7-2 FTA Ground-Borne Vibration Impact Criteria

Receptor Land use		RMS Vibration Levels (VdB)		
Category	Description	Frequent Events[1]	Occasional Events[2]	Infrequent Events[3]
1	Buildings where low vibration is essential for interior operations	65	65	65
2	Residences and buildings where people normally sleep	72	75	80
3	Daytime institutional receptors	75	78	83
	TV/Recording Studios/Concert Halls	65	65	65
Specific Buildings	Auditoriums	72	80	80
	Theaters	72	80	80

Notes:
1 "Frequent Events" defined as more than 70 vibration events of the same source per day. Most rapid transit projects fall into this category.
2 "Occasional Events" defined as between 30 and 70 vibration events of the same source per day. Most commuter trunk lines have this many operations.
3 "Infrequent Events" is defined as fewer than 30 vibration events of the same kind per day. This category includes most commuter rail branch lines.
Source: Federal Transit Administration, Transit Noise and Vibration Impact Assessment, FTA-VA-90-1003-06, May 2006.

For the section of the project corridor between Stoughton Station and Myricks Junction, the total number of daily train operations is 40 (20 northbound trains and 20 southbound trains). As a result, the

[3] The vibration impact analysis was performed by determining the distance from the rail corridor within which a vibration impact is expected to occur, using the typical vibration analysis methodology defined in the FTA guidance manual. The specific existing vibration levels were not measured at each of the 369 potentially impacted receptors under the Stoughton Alternatives, although typical existing conditions vibration information is provided in Table 4.7-1.

FTA vibration impact criterion for occasional events was used to assess impacts along this section of the rail corridor. For residential receptors that experience occasional train events, the FTA vibration impact level is 75 VdB. Note that this approach to the vibration criteria differs from the DEIS/DEIR vibration analysis where an 80 VdB impact threshold was used for all areas.

For the section of the rail corridor between Myricks Junction and New Bedford, and Myricks Junction and Fall River, the total number of daily train operations is 20 for each of these lines (10 northbound trains and 10 southbound trains). As a result, the FTA vibration impact criterion for infrequent events was used to assess impacts along these sections of the rail corridor. For residential receptors that experience infrequent train events, the FTA vibration impact level is 80 VdB.

The vibration criteria in Table 4.7-2 do not take into account situations where vibration impacts occur under existing conditions. To address areas with existing vibration impacts, the FTA guidance manual presents additional criteria for projects along existing passenger rail or freight corridors.

- For heavily used rail corridors (defined as greater than 12 trains per day), the proposed project is considered to cause a vibration impact if it approximately doubles the number of vibration events per day or increases vibration levels by 3 VdB or more in comparison to the existing condition. For the South Coast Rail project, this criterion applies to the Stoughton Line north of Stoughton Station, and the Northeast Corridor.

- For existing rail corridors with infrequent use (defined as fewer than five trains per day), FTA recommends that the standard vibration impact criteria be used (Table 4.7-2). The Fall River Secondary and New Bedford Mainline in the Southern Triangle are examples of infrequently used rail corridors under FTA's definition.

Based on the FTA's guidelines for existing rail corridors, there would be no vibration impacts along the Northeast Corridor or the active Stoughton Line, since there would be no increase in the vibration levels from the project. Adding an additional track to the existing rail corridor that would move the trains approximately 20 feet closer to the residences along the rail corridor would result in an increase in vibration levels of less than 3 VdB. For example, a train locomotive traveling at 50 mph would generate a vibration level of 78 VdB at a receptor located at a distance of 100 feet from the nearest track. If an additional track were added to the rail corridor that moved the trains 20 feet closer to the receptor, the vibration level would be 80 VdB at a distance of 80 feet from the nearest track. Since the addition of the new track would not result in an increase in vibration level of more than 3 VdB, in accordance with the FTA's guidelines for an active rail corridor, there would be no appreciable vibration impact from the addition of the new track. However, a more detailed vibration analysis should be performed during final design when drawings showing the location of the proposed new tracks are available and can be used to determine the distance to the nearest receptors.

4.7.3.3 Impact Assessment Methodology

The vibration assessment was prepared in accordance with the FTA's Transit Noise and Vibration Impact Assessment[4] guidance manual. The FTA guidance manual sets forth the basic concepts, methodology and procedures for evaluating vibration levels from transit operations. Key inputs included the distance between the receptors and track, train operating speed, and adjustments accounting for special track work (turnouts, crossovers etc.), as well as the propagation of vibration into buildings.

[4] FTA-VA-90-1003-06; May 2006

None of the alternatives have the potential to result in vibration levels that could cause minor structural damage (such as cracks in plaster walls) (e.g. 100 VdB for fragile buildings). Therefore, the focus of the analysis is on human annoyance from vibration based on the FTA criteria.

Generalized Base Vibration Curve

The FTA vibration model combines various algorithms with empirically developed ground surface curves to estimate transit vibration levels at various distances from the track for average soil conditions. FTA surface vibration curves (adjusted for speed) were used to predict ground-borne vibration levels from transit operations at receptor locations along each of the project alternative corridors (Figure 4.7-2). In general, vibration levels increase at higher train speeds. The FTA model was used to determine the impact distance from the rail corridor within which the project transit vibration levels would exceed the FTA impact criteria. As shown in Figure 4.7-2, vibration curves are specified for locomotives, lighter commuter rail passenger cars, and rubber tired vehicles (buses).

The FTA guidance manual indicates that the vibration levels generated by both diesel and electric locomotives use the same upper curve shown in Figure 4.7-2. As a result, the vibration impact assessment for both the diesel and electric alternatives for the South Coast Rail project would be the same, assuming the same operating speed. To be conservative, the slightly faster electric commuter rail speeds were assumed for the vibration impact analyses.

Using the electric train speed data along each section of the rail corridor, an impact distance was determined using the locomotive vibration curve (adjusted for train speed). The relationship between impact distance and train speed for the FTA impact criteria of 75 VdB and 80 VdB are shown in Table 4.7-3. These impact distances were then used in conjunction with the aerial photographs to determine the number and location of the impacted residential receptors.

Table 4.7-3 Impact Distance vs. Train Speed, Electric Alternatives

Train Speed	Impact Distance[1] to 80 VdB	Impact Distance[1] to 75 VdB
100 mph	160 feet	250 feet
90 mph	140 feet	230 feet
80 mph	130 feet	210 feet
70 mph	115 feet	185 feet
60 mph	100 feet	165 feet
50 mph	85 feet	140 feet
40 mph	70 feet	115 feet
30 mph	50 feet	90 feet
20 mph	32 feet	60 feet

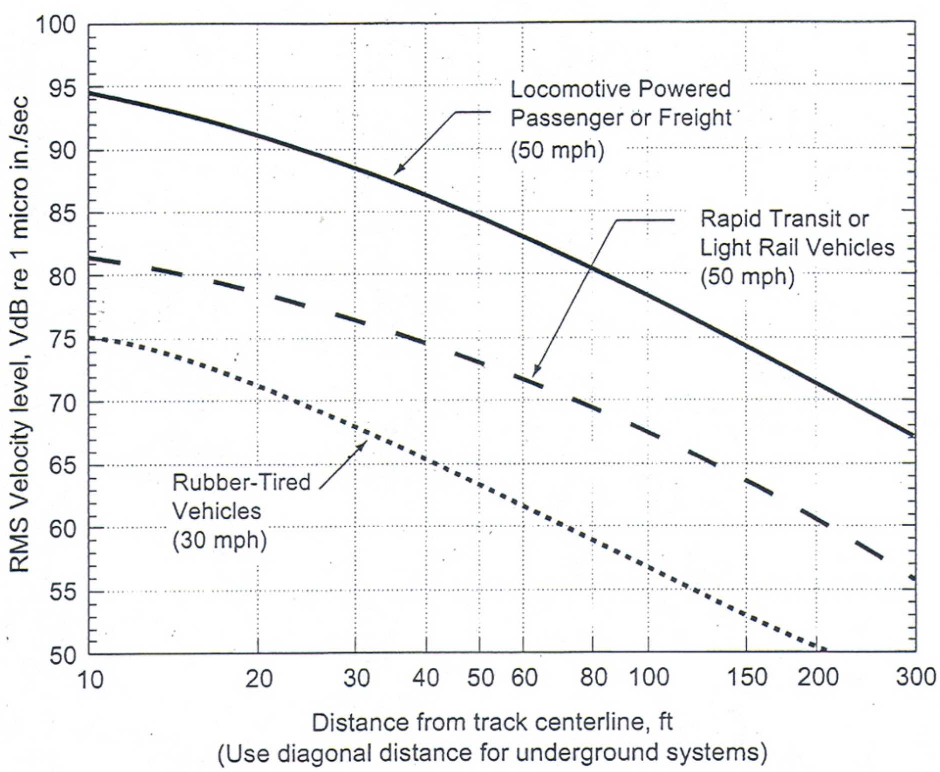
1 Distance from track centerline within which a vibration impact is expected to occur.

Ground Propagation

The vibration curves shown in Figure 4.7-2 are for generalized ground propagation characteristics. Although it is known that geographic conditions have a significant effect on vibration levels, it is rarely possible to develop more than a generalized assessment of the ground vibration propagation characteristics without a much more detailed vibration measurement program. For example, there are conditions where ground-borne vibration propagates much more efficiently than normal. Shallow

bedrock, less than 30 feet below the surface, is likely to have efficient propagation because much of the energy that would normally radiate down into the ground is reflected back towards the surface by the bedrock. The result is higher than normal ground surface vibration levels. Other factors that have an effect on vibration propagation are soil type and stiffness. In particular, stiff clay soils are also associated with efficient vibration propagation. However, the FTA recommends using the generalized ground propagation vibration curves in Figure 4.7-2 for Environmental Assessment and Environmental Impact Statement level analysis.

Figure 4.7-2 FTA Generalized Ground-Surface Vibration Curves



Source: Transit Noise and Vibration Impact Assessment, Federal Transit Administration, Washington, D.C., May 2006.

Special Trackwork

Trains traveling over switches or other special track work with gaps in the rail generate vibration levels that are 10 VdB higher than the levels indicated by the curves shown in Figure 4.7-2. For example, a locomotive traveling at a speed of 50 mph would generate a vibration level of 80 VdB at a distance of 80 feet from the tracks. A locomotive traveling at a speed of 50 mph over a switch would generate a vibration level of 80 VdB at a radial distance of approximately 225 feet from the switch. For the Build Alternatives, the vibration levels from switches located at each of the major junctions (Weir Junction, Myricks Junction, Cotley Junction, Whittenton Junction,) were evaluated, along with the switches associated with the proposed layover facilities.

The vibration impact assessment of the track switches along each of the project alternatives indicates that only one location has a receptor that is located within 225 feet of a switch that would result in a vibration impact of 80 VdB. A residential receptor on Ingell Street near Weir Junction would be exposed to a vibration level of 80 VdB during a train locomotive passby over the switch at Weir Junction. This impacted receptor is included in the vibration assessment for the Southern Triangle. No vibration impacts are expected to occur near any of the other switch locations associated with the other project alternatives.

Stations and Layover Facilities

At train stations and layover facilities, train-related vibration levels are generally significantly lower due to the slower train speeds. For example, a train traveling at a speed of 20 mph as it enters or leaves a train station would generate a vibration level of 80 VdB at a distance of 32 feet from the track. No vibration is generated while the trains are stopped at the stations. For a layover facility that has switches, a train traveling at 20 mph would generate a vibration level of 80 VdB at a radial distance of 100 feet from the switch. No vibration impacts were found at the two selected layover facilities (Weaver's Cove East and Wamsutta).

In the vicinity of the proposed train stations along each of the project corridors, acceleration and deceleration train speed profiles were used to account for trains stopping at the stations.

Track Condition

The vibration analysis assumed the use of continuous welded rail for each of the Build Alternatives. Continuous welded rail generates less vibration relative to other track configurations, such as jointed rail. In addition, since the heavier train locomotives generate higher vibration levels than the lighter passenger rail cars, the vibration analysis focused primarily on the vibration levels generated by the locomotives.

4.7.3.4 Impacts of Alternatives by Element

No-Build (Enhanced Bus) Alternative

The bus services added as part of the No-Build Alternative would not generate vibration levels sufficient to cause human annoyance assuming appropriate pavement maintenance over time.

Southern Triangle (Common to All Build Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all Build Alternatives. These rail lines form a rough triangular shape running south from Myricks Junction to Fall River (the Fall River Secondary) and from Weir Junction through Myricks Junction to New Bedford (the New Bedford Main Line), and are therefore referred to as the Southern Triangle. Although there is no commuter rail in the Southern Triangle, the existing tracks in this area are used by freight rail resulting in associated vibration levels under existing conditions, as described in Section 4.7.2.1.

As shown in Table 4.7-4, there are a total of 215 impacted receptors along the Southern Triangle section of the project corridor. The majority of the vibration impacts would occur in Fall River, where there is dense development in close proximity to the rail alignment. Eight of these impacted receptors are multi-unit apartment buildings and the rest are single-family homes. There are no institutional receptors or buildings with vibration sensitive equipment that would be impacted along the Southern Triangle. The general location of these impacted receptors (by municipality) is described in Table 4.7-5. Table 4.7-5 also shows the results of the vibration mitigation analysis for the impacted receptors along the Southern Triangle. The locations where ballast mats are recommended are shown in Figures 4.6-5f through 4.6-5i, and 4.6-4d through 4.6-4h in Chapter 4.6, *Noise* (the figures show both noise and vibration mitigation together to reduce the number of maps required).

* This impacted receptor is a multi-unit apartment buildings.

Stoughton Alternatives

The Stoughton Alternatives (Electric and Diesel) would provide commuter rail service to South Station using the Northeast Corridor, Stoughton Line, New Bedford Main Line, and Fall River Secondary.

Along the Stoughton line between Stoughton Station and Weir Junction, the vibration assessment indicates that there are a total of 154 impacted receptors (see Table 4.7-6). Eight of these impacted receptors are multi-unit apartment buildings and the rest are single-family homes. The general locations of these impacted receptors (by street) are described in Table 4.7-7. Table 4.7-7 also shows the results of the vibration mitigation analysis for the impacted receptors along the Stoughton Line. The locations where ballast mats are recommended are shown in Figures 4.6-6a through 4.6-6g in Chapter 4.6, *Noise* (the figures show both noise and vibration mitigation together to reduce the number of maps required).

There are no institutional receptors or buildings with vibration sensitive equipment that would be impacted by the Stoughton Alternatives. In addition, the vibration levels at the Easton Historic Train

Station (which experienced train-related vibration in the past) and other historic buildings in Easton Village would be below the 100 VdB vibration threshold for the onset of minor structural damage (such as small cracks in plaster walls) to fragile and historic buildings.

* This impacted receptor is a multi-unit apartment buildings.

Whittenton Alternatives

The Whittenton Alternatives (Electric and Diesel) would provide commuter rail service to South Station through Stoughton, connecting to the existing Stoughton Line using the Whittenton Branch through the City of Taunton.

The Whittenton Alternatives would result in 202 vibration impacts along the Stoughton Line, Whittenton Branch and Attleboro Secondary (see Table 4.7-8). Five of these impacted receptors are multi-unit apartment buildings on Bay Street in Taunton. The rest of the impacted receptors are single-family residences. There are no institutional receptors or buildings with vibration sensitive equipment that

would be impacted by the Whittenton Alternative. The general locations of the impacted receptors along the Attleboro Secondary and Whittenton Branch (by street) are shown in Table 4.7-9.

The vibration impacts along the Stoughton line in Stoughton, Easton, and Raynham are common to both the Stoughton and Whittenton Alternatives. The Whittenton Alternatives have greater total vibration impacts than the Stoughton Alternatives because of the dense development close to the Attleboro Secondary through downtown Taunton that is used by the Whittenton Alternatives, but not by the Stoughton Alternatives.

Table 4.7-8 Summary of Potential Vibration Impacts—Whittenton Alternative (Diesel and Electric)

As discussed in the methodology section, there would be no project related vibration impacts north of Stoughton Station.

4.7.3.5 Temporary Construction Impacts

Typical vibration levels from construction equipment at a reference distance of 25 feet are: 104 VdB for an impact pile driver; 87 VdB for a bulldozer; 86 VdB for a loaded truck; and 79 VdB for a jackhammer. In general, if most construction activity is located more than 75 feet from the nearest sensitive receptors, the estimated vibration levels would be expected to be below the FTA annoyance criterion of 80 VdB. However, pile driving is the major impact device that generates the highest vibration levels during construction. Pile driving located within 50 feet of a building could result in vibration impacts, if pile driving is required for this project. At this distance, the vibration levels from pile driving would be below the onset of minor building damage (cracks in plaster walls) threshold of 100 VdB for fragile buildings. To get the vibration levels below the human annoyance level of 80 VdB, the pile driving activity would require approximately 175 feet from the nearest sensitive receptor.

Construction-period vibration impacts would be assessed for each alternative during the final design phase, when construction methods and the locations of specific types of construction equipment have been identified.

During construction, if pile driving is required, vibration impacts can be reduced by pre-augering the hole so that the actual impact driving of the pile would only occur during the last few feet of installation. Another mitigation measure is sonic or vibratory pile driving (93 VdB at 25 feet), where the pile is vibrated into the ground eliminating the need for an impact hammer. These measures for reducing vibration impact would be considered in the development of construction plans for areas where pile driving could be required in proximity to sensitive receptors.

4.7.4 Summary of Impacts

The results of the vibration impact assessment for each of the South Coast Rail alternatives are summarized in Table 4.7-10. This summary includes the vibration impacts from the Southern Triangle from Weir Junction to New Bedford and Fall River that are common to all Build Alternatives.

The Whittenton Alternatives result in 48 more impacted receptors than the Stoughton Alternatives, with the Attleboro Secondary segment of the Whittenton Alternatives being the primary cause of the greater impacts. The noted vibration levels reflect annoyance and would not rise to a level considered to cause structural damage.

Table 4.7-10 Summary of Potential Vibration Impacts without Mitigation by Alternative

Alternative	Impacted Residences
No-Build (Enhanced Bus) Alternative	0
Stoughton Alternatives	369
Whittenton Alternatives	417

4.7.5 Mitigation

4.7.5.1 Overview of MBTA Vibration Mitigation Policy

The need for vibration mitigation in a specific location is determined based on the magnitude of the impacts and consideration of other factors such as feasibility and cost-effectiveness. The U.S. Army Corps of Engineers does not have mitigation evaluation criteria for commuter rail projects and therefore

relies on the guidance of the federal agency with special expertise in this area, the FTA. The FTA guidance requires consideration of mitigation for vibration impacts and outlines the available mitigation options. FTA allows transit providers to develop local agency-specific noise and vibration mitigation policies detailing the analysis process and criteria for their projects.

MBTA has developed a noise mitigation policy consistent with the FTA guidance (See Section 4.6.3.6). The MBTA noise mitigation policy establishes a cost effectiveness criterion of $30,000 per dwelling unit. MBTA also utilizes this same cost effectiveness criterion ($30,000 per benefited receptor) for assessing potential vibration mitigation measures.

4.7.5.2 Stoughton Alternatives Vibration Mitigation Plan

Several mitigation measures were assumed to be incorporated in the project design and were included in the vibration modeling analysis:

- Continuously welded rail would be used to minimize vibrations caused by wheels impacting rail joints.
- Ballast (the crushed rock under the tracks) and sub-ballast (gravel base) would be placed to standard depths established by the MBTA to reduce transmission of vibration from the tracks to the ground.
- Turnouts would be located at least 100 feet away from homes and other sensitive buildings, to minimize higher vibration levels due to passage of wheels over the gap in turnout frogs.
- Trains and track would be maintained in such a manner as to minimize vibration generated by the trains, including regular wheel re-truing to eliminate wheel flats.

Additional mitigation measures, such as ballast mats (rubber mats placed under the ballast) would be provided where vibration mitigation is justified, and soil conditions are appropriate, as determined by on-site inspection of each potential mitigation location. Ballast mats can give vibration reductions of between 3 and 10 VdB. Ballast mats are very effective in attenuating frequencies of greater than 100 Hz found in vibrations near the source, and for track-receptor geometries traveling through dense soil and rock. They are not particularly effective at attenuating lower frequencies, especially those in the 10-30 Hz range found at distances greater than 60 feet and expected at sites with soft or sandy soil conditions. Therefore, a more detailed evaluation of the source-receiver soil conditions would be required during final design to assess the effectiveness of the ballast mat at impacted receptor locations along the corridor. Ballast mats cannot be installed within 50 feet of grade crossings; exact distances from each grade crossing would be determined at the time of final design.

The vibration analysis identified a total of 369 residences likely to be impacted by the Stoughton Electric Alternative. Based on the length of the ballast mat, and the cost of this mat at $180 per track foot, a mitigation price was determined for each receptor location. Any mitigation priced more than $30,000 per receptor was considered to not be cost-effective, based on the same MBTA cost-effectiveness criteria used for noise impacts (see Section 4.6.3.6). Those under $30,000 were considered cost-effective. Of the total impacted receptors, 296 (39 locations) were considered to be cost-effective for vibration mitigation. Approximately 33,350 linear feet of ballast mat would be required along the rail corridor at a cost of approximately $6,003,000. The locations of the proposed ballast mats for the Stoughton Electric Alternative are discussed by town below.

Stoughton

Ballast mats were considered cost-effective at three locations in Stoughton (Figures 4.6-6a and 4.6-6b):

- along Brock Street/Washington Street;
- along Rogers Drive/Plain Street; and
- along Smyth Street/Washington Street.

Easton

Ballast mats were considered cost-effective at five locations in Easton (Figures 4.6-6b, 4.6-6d, 4.6-6e):

- along Center Street/Williams Street/Avis Circle/Baldwin Street;
- along Laurel Drive;
- along Short Street/Lantern Lane;
- along Kennedy Circle; and
- along Prospect Street.

Raynham

Ballast mats were considered cost-effective at five locations in Raynham (Figure 4.6-6f):

- Bridge Street;
- Elm Street West;
- Carver Street;
- Britton Street; and
- Wampanoag Road/King Phillip Street/Chickering Road.

Taunton

Ballast mats were considered cost-effective at five locations in Taunton (Figure 4.6-6g):

- along Thrasher Street/Malcolm Circle;
- along Summer Street;
- along High Street/Paul Bunker Drive;
- along Hart Street/Alegi Avenue; and
- along Williams Avenue/Plain Street.

Berkley

Ballast mats were considered cost-effective at three locations in Berkley (Figures 4.6-5f and 4.6-4d):

- along Padelford Street;
- along Mill Street; and
- along Adams Lane.

Lakeville

Ballast mats were not considered cost-effective in Lakeville.

Freetown

Ballast mats were considered cost-effective at four locations in Freetown (Figures 4.6-5h and 4.6-4d):

- along Braley Road;
- along Richmond Road;
- along Forge Road; and
- along High Street/Alexander Drive.

New Bedford

Ballast mats were considered cost-effective at three locations in New Bedford (Figure 4.6-5i):

- along Lynn Street; and
- along Purchase Street.

Fall River

Ballast mats were considered cost-effective at eleven locations in Fall River (Figures 4.6-4d-h):

- along Leeward Road;
- along Rolling Green Drive;
- along North Main Street;
- along Pickering Street/Clinton Street/St. James Street;
- along Murry Street/Cory Street/Ballard Street/Almy Street/Railroad Avenue/North Court Street/Brownwell Street/Thompson Street;
- along Dyer Road;
- along Durfee Street/Cedar Street;

- along Maple Street; and
- along Meadow Street.

For the impacted receptor located within 225 feet of the switch at Weir Junction, "frogs" (sections of railroad track at a switch that guide rail car wheels from one track to the other) with spring-loaded mechanisms can be used rather than conventional frogs without spring-loaded mechanisms. The spring-loaded mechanism closes the gaps between the running rails. This substantially reduces the vibration emanating from switches and thus eliminates the impact at this receptor.

4.7.5.3 Whittenton Alternatives Vibration Mitigation Plan

Along shared segments, the vibration mitigation under the Whittenton Alternatives would be the same as described above for the Stoughton Alternatives (e.g. Southern Triangle and portion of Stoughton Line). Table 4.7-11 below presents the vibration mitigation analysis for the Whittenton Branch and Attleboro Secondary portions of the Whittenton Alternatives. A total of 6,300 feet of ballast mat costing $1,134,000 was found to be cost effective for these segments.

Table 4.7-11 Whittenton Alternatives Vibration Mitigation—Whittenton Branch/Attleboro Secondary

Municipality	Street	Impacted Receptors	Length of Ballast Mat	Cost at $180/ft	Cost per receptor	Cost Effective
Raynham	King Philip Street	3	400 ft	$72,000	$24,000	Yes
Raynham	Regan Circle	2	400 ft	$72,000	$36,000	No
Taunton	Redwood Drive	3	600 ft	$108,000	$36,000	No
Taunton	Bay Street	5	700 ft	$126,000	$25,200	Yes
Taunton	Whittenton Street	4	2,300 ft	$414,000	$103,500	No
Taunton	Edwards Avenue	6	1,200 ft	$216,000	$36,000	No
Taunton	Horton Street	14	1,700 ft	$306,000	$21,857	Yes
Taunton	Granite Street	1	200 ft	$36,000	$36,000	No
Taunton	Walnut Street	15	900 ft	$162,000	$10,800	Yes
Taunton	Cohannet Street	10	900 ft	$162,000	$16,200	Yes
Taunton	East Walnut Street	20	1,000 ft	$180,000	$9,000	Yes
Taunton	Weir Street	8	700 ft	$126,000	$15,750	Yes
Taunton	Weir Avenue	2	400 ft	$72,000	$36,000	No
Total for Cost-Effective Segments			6,300 ft	$1,134,000		

4.8 CULTURAL RESOURCES

4.8.1 Introduction

This chapter identifies the effects to cultural resources that may result from implementing each of the proposed South Coast rail alternatives. This section describes the potential impacts to identified cultural resources within the Area of Potential Effect (APE) defined for the alternatives, as well as steps that may be taken to avoid, minimize, or mitigate any adverse impacts to significant historic and archaeological properties. Impact analyses are based on numerous cultural resource identification surveys that have been completed to date for the alternatives. Background information on the proposed South Coast Rail alternatives is provided in Chapter 3, *Alternatives*. The alternatives are shown in Figure 4.8-1.

4.8.1.1 Resource Definition

For the purposes of this assessment, "cultural resources" refer to historic above-ground buildings, structures, and areas/districts and below-ground archaeological sites and archaeologically sensitive areas within and adjacent to the various components of the alternatives.

Direct impacts to historic resources could occur during the construction phase from the physical alteration of buildings, structures, and landscape or setting components within areas/districts, including demolition. Indirect impacts on historic resources could result during construction and/or operations from elevated noise or vibration levels, changes to the visual setting, increased traffic, or other environmental conditions affecting historic buildings, structures, and areas/districts. Direct impacts to archaeological resources could result from ground-disturbing construction activities in places where recorded/documented and under-documented pre-contact/contact Native American and post-contact EuroAmerican resources are or could be present.

4.8.1.2 Methodology

The Corps methodology is described in Appendix C, Procedures for the Protection of Historic Properties[1] of 33 CFR Part 325 - Processing of Department of the Army Permits (Appendix C). Appendix C identifies the procedures to be followed by the Corps to fulfill the requirements set forth in the National Historic Preservation Act (NHPA), other applicable historic preservation laws, and Presidential directives as they relate to the regulatory program of the Corps (33 CFR Parts 320-334).

The central concept in the Corps methodology is the "Permit Area," as defined in Appendix C. The term "permit area" as used in Appendix C means those areas comprising waters of the United States that will be directly affected by the proposed work or structures and uplands directly affected as a result of authorizing the work or structures. The following three tests must all be satisfied for an activity undertaken outside the waters of the United States to be included within the "permit area":

- Such activity would not occur but for the authorization of the work or structures within the waters of the United States;
- Such activity must be integrally related to the work or structures to be authorized within waters of the United States. Or, conversely, the work or structures to be authorized must be essential to the completeness of the overall project or program; and,

[1] AUTHORITY: 33 U.S.C. 401 et seq., 33 U.S.C. 1344, 33 U.S.C. 1413.

- Such activity must be directly associated (first order impact) with the work or structures to be authorized.

Pursuant to Appendix C, the Corps District Engineer must take into account the effects, if any, of proposed undertakings on historic properties both within and beyond the waters of the United States pursuant to Section 110(f) of the NHPA. The District Engineer, where the undertaking that is the subject of a permit action may directly and adversely affect any National Historic Landmark, shall, to the maximum extent possible, condition any issued permit as may be necessary to minimize harm to such landmark.

In addition to the requirements of the NHPA, all historic properties are subject to consideration under NEPA.[2] The Corps implements NEPA through the CEQ regulations in 40 CFR 1500-1588, its own NEPA regulations (33 CFR Part 325, Appendix B), and the Corps' public interest review requirements contained in 33 CFR 320.4.

In addition to the Corps' methodology for complying with the NHPA, the methodology based on the regulations of the Advisory Council on Historic Preservation 36 CFR 800.16(d), implementing Section 106 of the NHPA of 1966 are used by the Corps and Cooperating Agencies (USEPA, FRA, FTA and FHWA) in complying with the NHPA. The regulations of the Advisory Council on Historic Preservation 36 CFR 800.16(d) refer to the APE, which defines the areas in which a proposed undertaking may have an effect on an historic property, and the type of effect that may occur.

As defined in the Council's regulations, the APE for a project is the geographic area or areas within which an undertaking may directly, indirectly, or cumulatively cause changes in the character of historic properties that make them eligible for listing in the National Register of Historic Places (National Register), if any such properties exist [36 CFR 800.2(c)]. A direct impact APE is established to include the geographic area in which historic properties would be altered or otherwise used by construction activities or impacts related to project operations. An indirect impact APE typically consists of a larger area where auditory, pollution, noise, recreational visitor usage vibration, visual, and/or other types of environmental impacts resulting from an undertaking might affect the qualities for which a historic property is eligible for or listed in the National Register.

The South Coast Rail alternatives include 12 categories of potential work and operations types that may result in permanent or temporary and direct or indirect effects. The work types and operations expected for the project are:

- Increased train traffic on existing active track segments
- Minor repairs or rehabilitation of existing track in active use
- Constructing an additional track on an existing active track segment
- Restoring track and train traffic on out-of-service or abandoned rights-of-way
- Constructing commuter rail stations
- Constructing overhead catenary to allow electrified train service

[2] 42 U.S.C. 4321-4347.

- Layover and maintenance facilities
- Construction staging and laydown areas
- Operations noise and vibration (including horn blowing)
- Increased traffic queuing, intersection changes

These work types and operations may or may not be restricted to individual alternatives. Some of the proposed routes for the alternatives overlap and it is effective to look at track or corridor segments when defining the APE. Furthermore, an undertaking's APE may differ for above-ground resources (e.g., historic structures, buildings, and landscapes), below-ground resources (e.g., archaeological sites), and locations that are of traditional cultural significance to a particular individual or group including Native Americans (Traditional Cultural Properties or TCPs). Additional varying components of the project may result in more than one APE for the undertaking.

The various South Coast Rail project APEs were established by the Corps in terms of project alternatives and segments, work and operations (i.e., electrified and diesel) types, and resource class (see June 5, 2009 letter and final APE statement included in Appendix 4.8-A). The Massachusetts State Historic Preservation Office (SHPO) concurred with the Corps' definition of the South Coast Rail project APEs in a letter dated July 2, 2009.

The Wampanoag Tribe of Gay Head/Aquinnah indicated that the Hockomock and Pine swamps are regarded as traditionally culturally sensitive lands. These two swamps are located in the towns of Easton, Raynham, and Taunton, and may be affected by the Stoughton Alternative or Whittenton Alternative. The Mashpee Wampanoag Tribe and The Narragansett Indian Tribe may also be interested in these and other traditionally culturally sensitive lands. Should a location(s) of traditional cultural significance be identified within the project study area by individual(s) and/or groups, including the above federally recognized Indian Tribes, through the Corps' consultation with these groups, then the APE for such a location and its eligibility as a TCP would be determined through consultation between the Corps and the individual(s) and/or groups. The determination and treatment of any TCPs would be included in the Programmatic Agreement (PA) for the cultural resources of the South Coast Rail project. The Draft PA is included as Appendix 4.8-A.

Historic Resources Methodology

The South Coast Rail project would have direct and indirect, temporary and/or permanent, impacts on above-ground historic resources. Factors with potential to cause effects to historic above-ground properties that were considered in the definition of the APE for historic resources include:

- Atmospheric—resulting from trucks and machinery dust and exhaust during construction and train exhaust particulates during operation
- Noise—resulting from a variety of construction activities, and train wheels and horns sounding during operation
- Physical modification or demolition—changes to historic properties including bridges, culverts, and stations from actions including, but not limited to, noise insulation and barriers that alter historic buildings or their setting

- Traffic—changes in traffic patterns and traffic increases around grade crossings and stations
- Vibration—from construction activities and train pass-bys during operation
- Visual (setting)—changes to existing cultural landscape resulting from new construction (e.g., site preparation, signal and electrification equipment, grade crossings, new and modified bridges, right-of-way fences, noise walls, new and modified stations, new layover facilities, changes in land use, reduction of parcel sizes), vegetation clearing, and introduction of trains on corridors where service has been suspended since 1958; and cumulative impacts

The South Coast Rail project baseline APE for historic resources and for TCPs as defined by the Corps is summarized in Table 4.8-1. The areas listed in Table 4.8-1 encompass the direct APE, defined as the construction limits of the project, as well as the indirect APE. If a previously recorded or potential historic district or cultural landscape was identified, the APE would be broadened as necessary to encompass the boundary of the entire resource.

Direct impacts to historic resources were evaluated using preliminary engineering concept plans of project elements to identify the locations of historic buildings, structures, and areas/districts that are listed, determined eligible by the SHPO, or determined eligible for the National Register by the Corps in consultation with the SHPO within the APE for direct project impacts related to construction activities.

Indirect impacts to historic resources were evaluated by using environmental analyses for relevant impact categories including atmospheric, noise, traffic, vibration, visual, and cumulative impacts.

Table 4.8-1 APE Definitions by Work Types and Operations and Resource Class

Work Types and Operations	Below-ground	Above-ground	Traditional Cultural Properties
Rail corridors, baseline	Area of direct impact for proposed construction activities	800 feet (400 feet to either side of centerline) for electrification, 800 feet (400 feet either side of centerline) for diesel routes	To be determined in consultation with the Tribes
Stations (including stations, parking lots, access roads, and associated features)	Area of direct impact for proposed construction activities	250 feet from perimeter of proposed facility boundary	To be determined in consultation with the Tribes
Layover and maintenance facilities (lot only)	Area of direct impact for proposed construction activities	250 feet from perimeter of proposed facility boundary	To be determined in consultation with the Tribes
Construction laydown and staging areas (lot only)	Area of direct impact for proposed construction activities	250 feet from perimeter of proposed facility boundary	To be determined in consultation with the Tribes
Road, temporary and permanent access to proposed facility	Area of direct impact for proposed construction activities	400 feet from proposed road centerline	To be determined in consultation with the Tribes
Road, intersections	Area of direct impact for proposed construction activities	400 feet on either side of the intersection centerline	To be determined in consultation with the Tribes

Atmospheric

Atmospheric effects are considered in relation to USEPA and MBTA studies of emissions (nitrous oxide) and particulates (soot) from train diesel exhaust during operations that could potentially damage historic buildings. Air quality analyses have shown impacts to be minor for commuter rail lines and they are expected to be minimal for the South Coast Rail alternatives.

Noise

The analysis of noise impacts presented in Chapter 4.6, *Noise*, reports that properties could be impacted during service by changes in cumulative noise levels caused by train operations along the right-of-way and at layover facilities, and by warning horn blowing starting one-quarter mile prior to and at grade crossings. The FTA's noise impact criteria establish three levels of noise impacts, including no impact, moderate, and severe. These impact levels are calculated based on existing and projected new noise exposure, and the receptor and surrounding land use. Noise exposure at sensitive receptors along the rail right-of-way is expected to vary from 52 Ldn at locations up to 900 feet, to 70 or more Ldn at locations less than 125 feet from the track. Severe impacts are anticipated at locations where modeling predicts that the project noise exposure would exceed the sound levels in the FTA's noise impact criteria.

As identified in Chapter 4.6, *Noise*, the majority of noise sensitive receptors for the South Coast Rail alternatives within 1,000 feet of the rail corridor are single family and multi-family residences. The following definitions were used for the South Coast Rail alternatives per land use and receptors categories in FTA May 2006, pp 3-7, 3-8:

- Category 1 (quiet essential element for intended purpose): none (per FTA definition)
- Category 2 (buildings where people sleep): houses, inns, historic districts with houses (many in South Coast Rail project APE)
- Category 3 (institutional land uses with day and evening uses): schools, churches, libraries, lodges (a few in South Coast Rail project APE)
- Other sensitive historic categories with quiet settings:
    - Parks (passive and meditative)—per FTA are sensitive receptors (one in South Coast Rail project APE)
    - Cemeteries—not discussed in FTA report; however, historic cemeteries are places where a quiet setting is expected

Based on the noise analysis, transportation, industrial, commercial structures; parks with active recreational uses; and golf courses were not considered sensitive noise receptors.

Based on intensive survey level information and the generalized (not building by building) noise analysis, residences in historic districts with noise impacts would be affected. Noise level may have an effect on historic resources if noise increases reach the severe threshold at properties where a quiet setting is an important characteristic of National Register eligibility. There are five historic resources in the project APE where natural quiet is integral to the National Register setting. These are: Peirce and Haskins

Cemetery (PAL LA.024); North Burial Ground (PAL FR.K, FR.C); Neck of Land Cemetery (PAL Ta.029, Ta.C); Mount Pleasant Cemetery (PAL Ta.262); and the Blue Hills Multiple Resource Area (PAL De.A, Ca.E).

Noise may also affect an historic property if it is residential and if soundproofing measures such as barriers, insulated windows, or new doors are proposed that would affect the setting or appearance of the building or the setting of a district. Temporary noise from construction activities associated with utility relocation, grading, excavation, track and stations work, and installation of systems components is anticipated to be short term and to occur mostly during the day.

Physical Modification or Demolition

Physical modification or demolition to historic properties may occur from the application of noise proofing (discussed above); building demolition; bridge and culvert demolition, repair, and replacement; and the replacement or demolition of existing railroad infrastructure.

Traffic

Traffic impacts that could affect the setting of historic resources during operations include additional traffic around stations at certain times of day, and vehicle queuing at grade crossings or traffic control device during train pass-bys. Major changes in traffic could introduce or dramatically increase vehicles where none or few existed and/or alter access to and from historic properties by vehicles and pedestrians. Temporary traffic changes that could affect the setting of historic resources during construction would consist of the introduction of large machinery and vehicles, and redirected traffic. Potential impacts are analyzed in terms of traffic study thresholds to determine what, if any, locations are expected to have significant levels of impact. Traffic impacts to historic properties are expected to be minor for the South Coast Rail alternatives.

Vibration

The analysis of vibration impacts presented in Chapter 4.7, *Vibration*, shows that properties would be impacted by vibration where vibration levels reach 80 VdB or above. Based on the FTA Generalized Ground-Surface Vibration Curves Table included in the chapter, properties within approximately 90 feet of the center line of a locomotive powered passenger or freight rail line could be impacted by vibration levels of 80 VdB or more. Vibration may impact historic resources if the vibration levels are sufficiently high to result in structural damage to a building or structure, which is a threshold of 100 VdB for minor damage to fragile buildings. The vibration analyses for each of the diesel and electric alternatives indicate that the vibration levels from train pass-bys are below the threshold to cause structural damage to surrounding buildings or structures. It should also be noted that most of the buildings or structures eligible for inclusion in the National Register are in a context of functioning passenger and/or freight railroads in the past.

Temporary vibration from pile driving during construction could generate structurally damaging vibration levels of 104 VdB or more within 25 feet of the work site. This would be anticipated in the vicinity of certain bridges only.

Visual (Setting)

The analysis of visual impacts presented in Chapter 4.5, *Visual Resources and Aesthetic Resources*, provides information regarding the certain types of project work with new or substantially increased

(beyond what is already present) modern elements that could potentially change the setting of historic properties. Elements that may have a permanent effect on viewsheds and setting of historic resources include: new catenary, traction power facilities, and other electrification infrastructure; vegetation clearing and grading along new or improved rights-of-way; new grade crossing and signal shed equipment; traffic controls and road realignment; new right-of-way fences; noise walls; new or enlarged parking lots, new layover facilities and other site/landscaping work; and modification or demolition of existing buildings and structures, or new construction. Temporary visual effects may occur from construction staging areas. The quality of visual impacts is influenced by land contours and terrain, existing vegetation that remains, the view along streets not blocked by buildings, and the presence of intervening buildings. Introduction of new visual elements that are not out of character, either inherently or with mitigation measures applied, to the historic character of adjacent historic resources or areas would have low to moderate impacts. High impacts would occur where new visual elements are out of character with factors that qualify an historic property for inclusion in the National Register.

Cumulative

Cumulative effects are defined as the result of incremental effects of the project when added to other past, present, and reasonably foreseeable future actions. Cumulative effects on cultural resources are expected to be minor for the South Coast Rail alternatives. A description of indirect effects and cumulative impacts is provided in Chapter 5.

Archaeological Resources Methodology

The South Coast Rail project baseline APE for below-ground archaeological resources as defined by the Corps is described below.

The APE for archaeological resources is the direct APE where ground disturbances are planned for the construction of project elements. These elements include the active and inactive railroad right-of-way and active road right-of-way segments; new station locations; new layover/maintenance facility(s); and any other ancillary work areas and land takings identified as part of the alternatives.

Preliminary engineering concept plans of project elements (dated 2009) were used to determine if recorded archaeological sites and sensitive areas occurred within areas scheduled for direct impact. Concept plans were used to further inform on the direct project impacts to recorded archaeological resources and areas defined as archaeologically sensitive. In areas that were deemed archaeologically sensitive, intensive (locational) survey was conducted to identify archaeological sites within the APE so that potential adverse effects to archaeological resources could be assessed.

The scope of the intensive locational survey was established for the preferred alternative through consultation between the Corps and MassDOT. The intensive archeological survey was completed in April 2013 and conclusions of the intensive survey are summarized in this chapter. The Corps' Scope of Work also indicated that the proposed intensive archaeological subsurface testing was subject to change based on continuing Corps tribal consultations with federally recognized Indian Tribes. The intensive survey did not include archaeological testing for TCPs that may be identified for the project during the ongoing Corps tribal consultations.

Table 4.8-2 presents the proposed and actual subsurface testing conducted for the sensitive project rights-of-way and Stoughton Line stations summarized above in the intensive survey research design. The Corps' proposed testing methodologies for sensitive right-of-way areas were refined using

information provided in the 2012 supplemental reconnaissance survey for the Whittenton Alternative and the review of the current project conceptual design track and station plans depicting existing topography and limits of work areas for the Stoughton and Whittenton Alternatives. The subsurface testing included manually excavated test pits and machine assisted trenches.

Table 4.8-2 Archaeologically Sensitive Areas, Testing, and Results

Project Alternative	Sensitivity Assessment	Results of Intensive (Locational) Survey
Stoughton and Whittenton Alternatives	10 Areas	5 post-contact sheet refuse deposits not NR eligible 3 post-contact sites, 1 pre-contact site, not NR eligible 7 precontact sites, NR eligible
Stoughton Alternatives only	3 Areas	2 post-contact sheet refuse deposit, not NR eligible 3 precontact sites, NR eligible
Whittenton Alternatives only	2 areas	4 pre-contact sites NR eligible

4.8.2 Existing Conditions

4.8.2.1 Historic Resources

The historic resources discussed in this section are the properties determined eligible for listing in the National Register by the Corps in consultation with SHPO. The characterization of existing conditions was undertaken in two phases of historic survey, along with supplemental survey information and National Register determinations by the Corps and SHPO. An initial historic resources reconnaissance survey was conducted that included the Stoughton Alternatives followed by supplemental surveys which included the Whittenton Alternatives as well as additional survey information on the Stoughton Alternatives. The reconnaissance surveys were designed to identify historic resources that may be eligible for listing in the National Register and previously designated historic properties that are listed in, determined eligible for, or considered by the SHPO to be eligible for inclusion in the National Register. The subsequent intensive survey collected information on potentially National Register-eligible historic resources and produced recommendations for eligibility. This section presents the results of the intensive survey for the Stoughton and Whittenton Alternatives (Appendix 4.8-B) and the determinations of National Register eligibility made by the Corps and the SHPO in their review of the intensive survey results and recommendations. A summary of historic properties subject to consideration for project effects is in Table 4.8-3. The Whittenton Alternatives are the same as the Stoughton Alternatives, except that it proposes to use the Whittenton Branch of the Stoughton Line. Historic properties associated only with the Whittenton Alternatives are located only in Taunton, and are discussed separately in the discussion of properties in Taunton. Properties surveyed for the Stoughton Alternatives only are identified as such in the following discussion; these properties are in Raynham (one property) and Taunton (nine properties).

The intensive survey for the Stoughton Alternatives identified areas/districts and individual properties within the APE for the rail corridor and proposed stations that meet any of the following characteristics:

- Properties listed in the National Register
- Properties previously determined eligible by the Massachusetts SHPO for listing in the National Register
- Properties eligible for listing in the National Register

- Designated National Historic Landmarks (NHL)

Table 4.8 3 presents a summary of the historic resources identified for the Stoughton and Whittenton Alternatives that were previously listed in or determined eligible for listing in the State and National Registers. One property, the Quechechan River Bridge in Fall River has been determined eligible through consensus by the SHPO and MassDOT since the DEIS/DEIR survey, and has therefore been added to this group. A summary of the number of identified historic properties in each category—NHL, National Register listed, or National Register determined eligible—is presented in Table 4.8 3.

Table 4.8-3 Summary of Historic Resources

Project Location	Resource Type	NR Eligible *	NR Listed or Previously Determined Eligible**	Not Eligible, Demolished or Out of APE*
Canton	Areas/Districts	2	1	1
	Individual	3	2	0
Stoughton	Areas/Districts	1	0	0
	Individual	3	3	1
Easton	Areas/Districts	4	2 [1 NHL]	0

* Historic Resources Intensive Survey, Evaluation and Effects, Table 4-2 (May 2013)
** Historic Resources Intensive Survey, Evaluation and Effects, Table 3-2 (February 2013)

The following summary addresses those historic resources that are listed in or determined eligible for the National Register, by the SHPO, for the rail corridors and stations in these two alternatives.

Lists of these properties are provided for each alternative, indicating their association with a proposed or existing station as defined by the project or a grade crossing identified on the project base maps. These lists are included in the Historic Properties Intensive Survey included as Appendix 4.8-B. The results are based on archival research and walkover surveys of project elements new to the South Coast Rail alternatives, as well as updates to previous assessments of project elements for the Stoughton Alternatives of the New Bedford/Fall River Commuter Rail Extension Project conducted in 2001. The

results of these tasks are summarized below by project alternative and town. The surveyed properties discussed below are mapped on Figures 4.8-2 through 4.8-16, and are labeled according to "Map No." These resources are described in greater detail in the Cultural Resources Reconnaissance Survey, Volumes III and IV and the Historic Resources Intensive Survey, Evaluation and Effects.

Stoughton Alternatives

The Stoughton Alternatives (diesel and electric) consist of the Stoughton Line (active and inactive CSX and commuter) railroad right-of-way, a short section of the Attleboro Secondary (active CSX) railroad right-of-way, six proposed stations (North Easton, Easton Village, Raynham Park, Taunton [Dean Street], and Taunton Depot and Stoughton), and two existing stations (Canton Center, and Canton Junction). The Whittenton Alternatives (diesel and electric) use the Whittenton Branch (inactive) railroad right-of-way and the Attleboro Secondary between Whittenton Junction and Weir Junction. One alternate station is associated with the Whittenton Alternatives, the Dana Street (Taunton) Station. All alternatives (Whittenton and Stoughton) use the Southern Triangle, including the New Bedford Mainline and the Fall River Secondary.

The Stoughton/Whittenton Alternatives results are discussed below from north to south by community, station site, and layover facility/traction power site. The surveyed properties discussed below are mapped in Figures 4.8-2 through 4.8-16.

Canton

Approximately 2.3 miles of the Stoughton Line rail right-of-way, one traction power facility, and two existing stations (Canton Junction Station and Canton Center Station), are located within Canton as part of the Stoughton Alternatives. The Stoughton Line rail corridor in Canton is not National Register-eligible.

The following historic properties located along the Stoughton Line in Canton are eligible for National Register listing. The Canton Junction Railroad Station (Map No. Ca.001) is a Richardsonian Romanesque style, granite and red sandstone building erected in 1892 that is located at 666 Sherman Street, immediately east of the Stoughton Line at the point where it diverges from the Amtrak Northeast Corridor. The Revere Copper Company Railroad Embankment (Map No. Ca.002) is a linear earth mound feature with a single stone culvert from 1835 that is set in a wooded area south of Canton Junction, between the Stoughton Line and Amtrak's Northeast Corridor. The Revere Copper Company Works Area (Map No. Ca.B) is a 33-acre, multiple-building, active industrial complex purchased by Paul Revere in 1801, that is located 800 feet southwest of the Stoughton Line at 104 Revere Street. A portion of the original Revere Copper Company lot line, which is currently used as a parking lot, extends into the APE. The area was the site of the first copper rolling mill in the United States. The Washington Street Commercial and Institutional Area (Map No. Ca.C) is a neighborhood of approximately 55 commercial, civic, and residential buildings centered on Washington Street that straddles the Stoughton Line between Church Street to the south and Chapel Street to the north. It encompasses the Canton Center Area (Map No. Ca.H) and the Canton Public Library (Map No. Ca.006). The library is a cruciform-plan, limestone and brick, Classical Revival style building constructed in 1901 that is located at 786 Washington Street, approximately 600 feet north of the Stoughton Line. The Forge Pond Railroad Bridge (Map No. Ca.007) carries the Stoughton Line over a short waterway connecting Forge Pond and Kinsley Pond and is a single span stone arch and reinforced concrete bridge built between 1845 and 1890. The Canton Water Works (Map No. Ca.024) is a Romanesque-style industrial building constructed circa 1835 that is located at 44 Pine Street approximately 100 feet northeast of the Stoughton Line.

One traction power facility is proposed within Canton as part of the Stoughton Alternatives.

- TP-02, Switching Station (SWS-1) is located near a late-twentieth century residential subdivision, with a proposed access road that would extend through the driveway of an industrial loft (not eligible). A National Register-eligible stone and concrete arch Forge Pond Railroad Bridge (Ca.007), constructed between 1845 and 1890, is located to the northeast of TP-02.

Stoughton

Approximately 4.1 miles of the Stoughton Line rail right-of-way with one existing and one proposed station are located within Stoughton as part of the Stoughton Alternatives. No proposed traction power sites are within Stoughton as part of the Stoughton Alternatives. The existing Stoughton Station is located at Wyman Street and the proposed North Easton Station site is located in Stoughton at the town boundary with Easton. The Stoughton Line rail corridor in Stoughton is not National Register-eligible.

The following historic properties are located along the Stoughton Line in Stoughton. The Downtown Stoughton Area (Map No. St.B) radiates out from Stoughton Station and consists of approximately 386 properties developed with civic, commercial, industrial, and residential buildings between the mid-19th through the mid-twentieth century. The area is eligible for National Register listing. The Pearl Street Cemetery (Map No.St.022) is the oldest burial ground in Stoughton and is located approximately 1,100 feet northeast of the Stoughton Line near the town center. It consists of a 1.6-acre lot with approximately 400 burial markers from 1737 to 1965 and is eligible for National Register listing. The Stoughton Town Hall (Map No. St.023) is a Romanesque Revival style building constructed in 1881 that is located at 10 Pearl Street, approximately 400 feet northeast of the Stoughton Line and 600 feet from Stoughton Station. It has been determined eligible for National Register listing. The Mystic Rubber Company Building (Map No. St.024) is a brick mill loft constructed in 1877 that is located at 2 Canton Street, on the southwest side of the Stoughton Line near Stoughton Station and the Wyman and Porter street railroad crossings. It is eligible for National Register listing. The Stoughton Old Colony Railroad Station (Map No. St.025) is a National Register-listed Romanesque Revival style granite building constructed in 1888 that is located at 45-47 Wyman Street, near the Wyman Street railroad crossing serving the Stoughton Line. The Lucius Clapp Memorial Library (Map No. St.026) is a National Register-listed Classical Revival style brick building constructed in 1903 that is located at 6 Park Street, approximately 600 feet northeast of the Stoughton Line at Stoughton Station and the Wyman Street crossing. The Meade Rubber Company Building (Map No. St.046) is a brick mill loft constructed in 1916 that is located at 25 Brock Street on the west side of the Stoughton Line and an existing layover facility, and adjacent to the Brock Street railroad crossing. It is determined as eligible for National Register listing.

Stoughton (Proposed Station)

The proposed relocated Stoughton Station is not within any National Register Historic District or Area, and is south of the downtown Stoughton area (eligible for listing). The site contains one property that has been determined eligible for listing in the National Register: the Meade Rubber Company Building (MHC No. STG.1) at 25 Brock Street. The building is a two-story brick mill loft constructed in 1916 with arched window openings and brick piers. The company manufactured shoe heels and soles as well as rubberized fabrics for use in hospital sheets. Meade Rubber Company was one of several companies engaged in the rubber fabric industry in Stoughton in the early twentieth century. The Meade Rubber Company Building is potentially eligible for National Register listing at the local level under Criteria A and

C for its associations with the locally significant rubber industry as an intact example of an early twentieth century industrial loft. The proposed relocated station would require that this building be demolished, resulting in an adverse effect.

Easton

Approximately 6.6 miles of the Stoughton Line rail right-of-way, two traction power sites and one station, the Easton Village Station, are located in Easton as part of the Stoughton Alternatives. The Stoughton Line rail corridor is not National Register eligible, with the exception of approximately 2,000 feet of the Stoughton Line that is part of the Dighton and Somerset/Old Colony Railroad, Fall River Line Railroad Corridor (Map No. Ea.A) right-of-way that extends through the existing North Easton National Register Historic District. This portion is National Register-eligible as a contributing element of the historic district.

The following historic properties located on the Stoughton Line in Easton are listed in the National Register. The H.H. Richardson Historic District of North Easton (Map No. Ea.D) is a noncontiguous NHL district of five properties containing Richardson Romanesque style buildings designed by Henry Hobson Richardson. The Oliver Ames Free Library (1877) and Oakes Ames Memorial Hall (1879) are located on Main Street, approximately 400 feet west of the proposed Easton Village Station on the Stoughton Line. The Old Colony Railroad Station (1881) is located immediately north of the proposed station and directly abutting the rail right-of-way. The two remaining structures that comprise the NHL are outside the APE. The North Easton Historic District (Map No. Ea.B) encompasses the Stoughton Line between Main and Elm streets, and the proposed Easton Village Station. The district is listed in the National Register and includes approximately 160 buildings and six landscapes that date from the late eighteenth to the early twentieth century, including the Ames Company Shovel Shop complex located adjacent to the proposed Easton Village Station. The Stoughton Line right-of-way (Map No. Ea.A) track structure—including bridges, cuts and fills; retaining walls; and signal infrastructure—is important to the setting of this district. The Old Colony Railroad Station (Map No. Ea.003), located on the east side of the Stoughton Line between the Oliver Street grade crossing to the north and the proposed Easton Village Station to the south, is an H.H. Richardson Richardsonian Romanesque granite and brownstone building constructed in 1881. The station is individually listed in the National Register and is a contributing property to the H.H. Richardson Historic District NHL and the North Easton Historic District.

The following historic properties located on the Stoughton Line in Easton are eligible for National Register listing. The Holmes-Linden Street Area (Map No. Ea.C) encompasses approximately 400 feet of the Stoughton Line and consists of approximately 78 simple, wood-frame residences constructed in the mid- to late-nineteenth century to house laborers employed at the Ames Shovel Works and nearby shoe factories. The Center Street Area (Map No. Ea.E) encompasses approximately 0.5 mile of the Stoughton Line and includes approximately 343 wood-frame houses that demonstrate the expansion of North Easton out from its center at the Ames Company Shovel Shop complex from the early nineteenth to the early twentieth century. The Easton Center Area (Map No. Ea.F) encompasses approximately 0.5 mile of the Stoughton Line right-of-way and includes 120 civic and residential buildings from the late eighteenth through the twentieth centuries. The Hayward-Pool Area (Map No. Ea.G) abuts approximately 1,000 feet of the Stoughton Line at its west edge. It contains residences, a cranberry bog with associated agricultural buildings, and a burial ground developed between 1778 and 192. The Stoughton Line: Dighton and Somerset/Old Colony Railroad, Fall River Line Railroad Corridor (Map No. Ea.A) is an inactive section of the Stoughton Line right-of-way, originally constructed in 1866. Because of the poor integrity and condition of the Stoughton Line corridor, it is not as eligible for the National Register as an

independent historic district. However, the 2,000 foot-long portion of the Stoughton Line railroad right-of-way within the North Easton Historic District (MHC Nos. EST.E and EST.B) between Main and Elm streets is eligible for the National Register as a contributing element to the existing North Easton Historic District.

Two proposed traction power sites are located in Easton as part of the Stoughton Alternatives.

- TP-03, Paralleling Station (PS-1) is located south of the proposed North Easton Station, near a shopping center and contemporary residential subdivisions. No National Register listed or eligible historic properties have been identified in the APE.

- TP-04, Substation (TPSS-1) is located in a forested area near Hockomock Swamp. One National Register eligible historic property has been identified in the APE.

Raynham

Approximately 4.9 miles of the Stoughton Line and 1.2 miles of the Whittenton Branch rail rights-of-way, along with one proposed station, the Raynham Park Station, are located within Raynham as part of the alternative. The Raynham Park Station is on the Stoughton Line near the Easton town boundary. There are no proposed traction power sites in Raynham. The portion of the Stoughton Line rail right-of-way corridor located in Raynham is not National Register eligible.

The following properties along the Stoughton Line and Whittenton Branch in Raynham are eligible for National Register Listing. The Carver Street Area (Map No. Ra.B) is located on the east side of the Stoughton Line at the Carver Street railroad crossing and consists of six civic, religious, and residential properties constructed between 1865 and 1905. The Broadway-Center Street Area (Map No. Ra.C), which is centered on Broadway (State Route 138), encompasses portions of the Stoughton Line and abuts the west side of the Whittenton Branch. The area includes residential, commercial, and civic properties constructed between approximately 1860 and 1960. The Dog Kennel and Track Property (Map No. Ra.011) is located at 385 Thrasher Street along the east side of the Stoughton Line near the Britannia Street railroad crossing and the Taunton city boundary. It includes a wood-frame farmhouse constructed circa 1870, a fenced kennel and dog run complex, and a large, oval dirt track with an announcer’s podium that abuts the railroad.

The property at 521 (formerly 87) Prospect Hill Street (Map No. Ra.001) is a farmstead that extends between Prospect Hill Street and the west side of the Stoughton Line, and includes a wood-frame house constructed circa 1890 and several outbuildings. The property is eligible for listing in the National Register.

Approximately 0.7 mile of the New Bedford Main Line rail right-of-way extends through Taunton. There are no properties listed in, or determined as eligible for the National Register along the New Bedford Main Line in Taunton. Approximately 2.0 miles of the Stoughton Line is located within Taunton as part of the Stoughton Alternatives, as well as approximately 1.6 miles of the Attleboro Secondary rail right-of-way between Weir Junction and Cotley Junction that connects the Stoughton Line to the New Bedford Main Line. Two new stations are proposed in Taunton for the Stoughton Alternatives: Taunton (Dean Street) and Taunton Depot, as well as one traction power site (TP-05, Paralleling Station PS-2). The portion of the Stoughton Line rail corridor located in Taunton has been determined not eligible for the National Register.

The Taunton Multiple Resource Area (MRA) (Map No. Ta.C) includes five National Register Historic Districts and 87 properties individually listed in the National Register, which are located within the city limits of Taunton. The South Coast Rail project APE encompasses one historic district and 10 individual properties included in the Taunton MRA.

The following properties located between the Raynham town boundary and the junction of the Stoughton Line with the Attleboro Secondary are listed in the National Register. These properties are all within the Taunton Center Area (Map No.Ta.B, see below). The Dean-Hartshorn House (Map No. Ta.018, Ta.C) is a Georgian style building constructed circa 1798 that is located approximately 600 feet east of the Stoughton Line at 68 Dean Street. The Old Colony Railroad Station (Map No. Ta.019, Ta.C) is a brick structure constructed in 1876 that is located on the west side of the Stoughton Line between the Dean Street railroad crossing and the proposed Dean Street Station. The William Woodward House (Map No. Ta.020, Ta.C) is a Federal style house constructed circa 1830 that is located at 117 Arlington Street, approximately 200 feet west of the Stoughton Line, near the Dean Street crossing and the proposed Dean Street Station. The house was originally located on Dean Street, where it was used as a depot by the Old Colony and Newport Railroad from 1866 to 1881. The Charles R. Atwood House (Map No. Ta.021, Ta.C) is an Italianate style, wood-frame building constructed circa 1850 that is located at 30 Dean Street, approximately 400 feet west of the Stoughton Line near the Dean Street railroad crossing. The Theodore Dean House (Map No. Ta.022, Ta.C) is a wood-frame building constructed in 1866 that is located approximately 500 feet west of the Stoughton Line at 26 Dean Street. The C.J. H. Bassett House (Map No. Ta.023, Ta.C) is an irregular-plan Gothic Revival style wood-frame building constructed in 1851 that is located approximately 950 feet west of the Stoughton Line at 20 Chestnut Street. The Abiezar Dean House (Map No. Ta.028, Ta.C) is a Federal style wood-frame building constructed circa 1835 that is located approximately 800 feet west of the Stoughton Line at 57 Summer Street. The Neck of Land Cemetery (Map No. Ta.029, Ta.C), which dates from 1687 to 1889, is located on Summer Street, approximately 100 feet west of the Stoughton Line. The cemetery is Taunton's oldest burial ground and contains the graves of many of Taunton's early prominent figures.

The following properties located between Raynham Junction (the Raynham town boundary) and Weir Junction (the junction of the Stoughton Line with the Attleboro Secondary) are eligible for National Register listing. The Taunton Center Area (Map No. Ta.B) is a large, irregularly shaped area located along the north and west sides of the Taunton River east and west of the Stoughton Line. It encompasses the Church Green National Register Historic District (outside the APE), the larger Church Green Local Historic District (within the APE), and the Ashland Street Area (within the APE, no map number). The High Street Area (Map No. Ta.D) is a residential neighborhood bounded by the Mill River to the north, the Stoughton Line to the east, the Attleboro Secondary to the south, and Winthrop Street to the west. It encompasses approximately 200 properties, the majority of which are Victorian period residences constructed between 1870 and 1910.

Whittenton Alternatives

The Whittenton Alternatives diverge from the Stoughton Alternatives at Raynham Junction in the Town of Raynham and extends 2.1 miles along the Whittenton Branch to Whittenton Junction, where it follows the Attleboro Secondary for 2.4 miles to Weir Junction, at which point the two alternatives are identical.

One property on the Whittenton Branch in Taunton is listed in the National Register. The Whittenton Mills Complex (Map No. Ta.G, Ta.C) is bounded by the Whittenton Branch right-of-way to the east, Whittenton Street to the south, and the Mill River to the west. The 20-acre industrial complex contains

ten major attached and freestanding brick and wood-frame industrial buildings dating from circa 1858 to 1895.

The following properties on the Whittenton Branch and Attleboro Secondary in Taunton are eligible for National Register listing. The Whittenton Mills Area (Map No. Ta.F) is centered on Whittenton Street, east of the Mill River, and located east and west of the Whittenton Branch. The area encompasses approximately 80 properties developed with worker housing and industrial buildings associated with the National Register listed Whittenton Mills Complex (Map No. Ta.G) discussed above. The Reed and Barton Mill Village (Map No. Ta.H) is a compact neighborhood of worker housing located along Meadow, Cottage, and Lawrence streets, to the southeast of Whittenton Branch near the proposed Whittenton Station site. It encompasses approximately 87 wood-frame residences constructed between the mid- to late nineteenth century. The Ancient Whittenton Area (Map No. Ta.I) is a linear area located on Whittenton and Warren streets that intersects the Whittenton Branch at the Warren Street railroad crossing and encompasses approximately 40 properties from the eighteenth and nineteenth century. Cohannet Mills No. 3 (Map No. Ta.089) located at 120 Ingell Street, is a rectangular, 426-foot by 107-foot, multi-bay, brick loft constructed in 1890 with a flat roof, segmental arch windows, a granite block foundation, and slow-burning interior construction. A boiler/engine house with a round brick chimney is attached to the west side of the building. Mill No. 3 is the only surviving building of three cotton spinning plants built in Taunton by Cohannet Mills. The mill was recently rehabilitated into 64 loft apartments. The Cohannet Mills No. 3 was individually listed in the National Register in 2006. The N.S. Mason House (Map No. Ta.181, Ta.C) is a two-and-one-half-story, wood-frame, front gabled, Italianate style house constructed circa 1865. The N.S. Mason House was listed in the National Register at the local level under Criteria A and C as part of the 1984 Taunton MRA, for its associations with the nineteenth-century development of Taunton and as an example of the Italianate style.

The St. Thomas Episcopal Church (Map No. Ta.208, Ta.C)is located at 111-115 High Street is a Gothic Revival style stone church with a basilica plan designed by Richard Upjohn and constructed between 1857 and 1859. The church retains coursed granite walls, limestone trim, buttresses, pointed arch windows, and round stained glass clerestory windows. The McKinstrey House (Map No. Ta.209, Ta.C) property is a two-story, five-bay by two-bay, Georgian style brick house constructed circa 1760.The house is currently used as the St. Thomas Episcopal Church rectory. The McKinstrey House was listed in the National Register as part of the 1984 Taunton MRA. The Henry G. Brownell House property (Map No. Ta.211, Ta.C) is a two-and-one-half story, three-bay-wide, Classical Revival style, wood-frame building constructed by local builder L.M. Witherell for Henry G. Brownell in 1893. The Henry G. Brownell House was listed in the National Register as part of the 1984 Taunton MRA. The Lord-Baylies-Bennett House (Map No. 245, Ta.C) is a one-and-one-half story, five-bay-wide, stone, Greek Revival style building constructed in 1831 with a portico. It retains its historic, low-pitched front gable roof with four interior brick chimneys, floor length rectangular window openings, stone lintels, and a central entrance with a transom and side lights. The portico has recessed panels on the cornice and is supported by 12 Doric columns. The Lord-Baylies-Bennett-House was listed in the National Register as part of the 1984 Taunton MRA. The Samuel Washburn House (Map No. 246, Ta.C) is located at 68 Winthrop Street is a two-story, three-bay by two-bay, Italianate style stone villa constructed circa 1860. The house retains its original near-flat hipped roof with deep overhanging eaves, stuccoed walls, and a cornice line belt course. The Samuel Washburn House was listed in the National Register as part of the 1984 Taunton MRA.

The Samuel Colby House (Map No. 254, Ta.C) is located at 74 Winthrop Street. The house is a two-story, three-bay by four-bay Italianate style, stone and stucco mansion constructed circa 1869. The building

retains its original flat roof with a rectangular belfry, overhanging bracketed eaves, rectangular window hoods; and a full-width, one-story Stick style porch. The Sarah A. Haskins House (Map No. Ta.259, Ta.C, Ta. D, Ta.V) is located at 18 Harrison Street. The house is a two-and-one-half story, three-bay-wide, Italianate style, wood-frame house was constructed circa 1852 with a front gable roof and stone foundation. The property is also located within the National Register eligible High Street area which incorporates the surveyed Harrison Street area (Map Nos. Ta.D and Ta.V). The Mount Pleasant Cemetery (Map No. Ta.262) is located at 19 Crocker Street. The cemetery encompasses an approximately 10-acre polygonal lot and contains more than 500 burials dating from 1710 through the mid-twentieth century. At least one-quarter of the plots in the cemetery are the burial sites of soldiers from the American Revolution, War of 1812, Civil War, Spanish-American War, World War I, World War II, and the Korean War. The J. C. Bartlett House (Map No. Ta.266, Ta.C) is located near the Winthrop Street grade crossing, at 12 Walnut Street. The house is a two-and-one-half-story, three-bay-wide, Second Empire style, wood-frame building constructed circa 1880. The J. C. Bartlett House was listed in the National Register at the local level under Criteria A and C as part of the 1984 Taunton MRA. The Albert Field Tack Works (Map No. Ta.293, Ta.C, Ta.Y, Ta.D) is located at 19 Spring Street. The Albert Field Tack Works consists of a two-and-one-half story, three-bay-wide, Italianate style brick office constructed in 1868, attached to a two-story brick loft with an exterior stair tower. The office has a central, pedimented bay with a round arched entrance set within an entrance porch. The tower has a steeply pitched hip roof with pedimented dormers.

The H. B. Lothrup Store (Map No. Ta.294, Ta.C, Ta.D) is located approximately 500 feet northeast of the Attleboro Secondary right-of-way on the Whittenton Alternatives, at 210 Weir Street. The house is a two-and-one-half story, three-bay-wide Italianate style, wood frame building constructed circa 1855 with a front gable roof and clapboard siding. The William Lawrence House (MHC No. TAU.334) is a two-and-one-half story, three-bay-wide, Second Empire style wood-frame mansion constructed circa 1870 and retains its original mansard roof with a rectangular belfry, shallow brackets and dentils, and arched dormers; clapboard siding, rectangular windows with protruding lintels, and granite foundation. A one-story full-width porch extends across the facade and defines a central entrance with a round-arched opening.

Dana Street Station

The Dana Street Station is proposed on a parcel between Dana Street and the Attleboro Secondary in Taunton. Dana Street replaces the Downtown Taunton Station that was previously under consideration at a different location. The Taunton State Hospital property (Map No. Ta.S), which is listed in the National Register, is located on the opposite side of Dana Street to the east. The Staples Coal Company (Map No. Ta.160) is located at 28 Dana Street south of the station APE.

Southern Triangle: New Bedford Main Line and Fall River Secondary

The Southern Triangle consists of the existing Fall River Secondary (active MassCoastal) railroad right-of-way, the existing New Bedford Main Line (active MassCoastal) railroad right-of-way, and five proposed stations: Freetown, Fall River Depot, Battleship Cove, King's Highway, and Whale's Tooth. The Southern Triangle also includes four proposed layover facility sites (one in Freetown, two in New Bedford and one in Fall River) and seven proposed traction power sites located along the existing Fall River Secondary (active MassCoastal) and the existing New Bedford Main Line (active MassCoastal) railroad rights-of-way in Berkley, Freetown, New Bedford, and Fall River. The Southern Triangle is common to both the Stoughton and Whittenton Alternatives.

The Southern Triangle results are discussed below from north to south by community and station, and are listed in the Historic Resources Intensive Survey, Appendix A. The surveyed properties discussed below are mapped on Figures 4.8-9 through 4.8-16. The following are descriptions of the areas/districts and individual properties identified during the survey as either listed in or determined eligible for listing in the National Register. No properties within the APE in the Southern Triangle have been designated as NHLs.

Berkley

Approximately 2.8 miles of the New Bedford Main Line and 0.7 mile of the Fall River Secondary rail rights-of-way, and one traction power site, are in Berkley as part of the Stoughton Alternatives. The junction of the New Bedford Main Line and Fall River Secondary with grade crossings at Myricks and Mill streets occurs within the Myricks Area (Map No. Be.C), a nineteenth-century railroad village. The New Bedford Main Line passes within 50 feet of 1 Macomber Street (Map No. Be.006) at the Padelford Street grade crossing, which is an Italianate style farmhouse constructed circa 1860. Both properties are eligible for National Register listing.

One traction power site (TP-06/TP-27) is proposed in Berkley as part of the Stoughton and Whittenton Alternatives.

- TP-06, Switching Station (SWS-2) as part of the Stoughton and Whittenton Alternatives, is located at the Myricks Street grade crossing of the New Bedford Main Line, within the National Register-eligible Myricks Area of mid-nineteenth- to early-twentieth-century residences (Map No. Be.C).

Lakeville

Approximately 3.5 miles of the New Bedford Main Line and 0.3 mile of the Fall River Secondary Line rail rights-of-way are in Lakeville as part of the Stoughton Alternatives. The Pierce and Haskins Cemetery (Map No. La.024), which is located 200 feet east of the Fall River Secondary right-of-way and is accessible from Adams Lane in Berkley, contains approximately 45 slate and granite headstones dating from 1785 to 1892. Bridge No. 18.37 Over the Assonet River (Map No. La.025), constructed in 1906, carries the Fall River Secondary over the Assonet River in Lakeville and is a rare surviving example of a two-span timber deck railroad bridge with timber abutments. The Assonet Cedar Swamp Area (Map No. La.C) in Lakeville is a cultural landscape encompassing the majority of the New Bedford Main Line that extends through Lakeville. It is comprised of approximately 2,670 acres of natural resources and cultural resources dating from the early eighteenth to early twentieth century. These three properties are eligible for National Register listing.

There are currently no proposed layover facilities or traction power sites in Lakeville. One bridge noted as having insufficient information in the March 2009 report, Bridge over Cedar Swamp River (Map No. La.022, Photo No. 237), was surveyed and found to not be National Register eligible.

Freetown

Approximately 3.5 miles of the New Bedford Main Line and 5 miles of the Fall River Secondary rail rights-of-way, two traction power sites, one layover facility and the proposed Freetown station, are in Freetown as part of the Stoughton Alternatives. The Richmond Road/Maple Tree Crossing Bridge (Map No. Ft.009), situated approximately 100 feet north of the Fall River Secondary Line near the grade

crossings at Richmond and Beechwood roads, is a dry-laid stone three-arch structure built in 1820–1824 and determined eligible for National Register listing. The National Register-listed Assonet Historic District (Map No. Ft.D) on the Fall River Secondary Line is a town center dating from 1720 to the mid twentieth century. It encompasses one property, a cattle pound, which extends into the APE. The Slab Bridge Road Area (Map No. Ft.C) is adjacent to or overlaps three grade crossings on the Fall River Secondary and is an intact neighborhood of late 18th to early twentieth century residential architecture.

Two traction power sites (TP-08 and TP-10) are proposed in Freetown as part of the Stoughton Alternatives.

- TP-08, Paralleling Station (PS-3), is located in a forested area on the New Bedford Main Line, near an existing electrical transmission line. There are no National Register listed or determined eligible properties in the APE.

- TP-10, Paralleling Station (PS-4), is located at the Copicut Road grade crossing of the Fall River Secondary rail right-of-way. No National Register listed or eligible historic properties have been identified in the APE.

New Bedford

Approximately 7.4 miles of the New Bedford Main Line rail right-of-way, three traction power sites, one layover facility and two stations—King's Highway and Whale's Tooth—are located in New Bedford as part of the Stoughton Alternatives. All the historic resources identified in New Bedford are along the New Bedford Main Line and south of Route 140. In the general vicinity of King's Highway Station between Route 140 and King's Highway Station/Tar Kiln Road, is the massive, reinforced concrete Belleville Warehouse Company Cotton Storage Building (Map No. NB.012) constructed in 1916. The warehouse is located on the east side of the New Bedford Main Line near the Nash Road railroad crossing and was determined eligible for National Register listing by the Keeper of the National Register. The following resources are eligible for listing in the National Register. The Manomet Mills Cotton Mill No. 4 (Map No. NB.011), located at 91 King Street on the east side of the New Bedford Main Line, is a brick loft constructed in 1920 for the purpose of spinning cord tire fabric. The Lambeth Rope Corporation Complex (Map No. NB.010) is a brick loft constructed between 1894 and 1918 to manufacture pulley ropes for textile mills, and is located at 627 to 637 Tarkiln Hill Road along the west side of the New Bedford Main Line, near the Tarkiln Hill Road railroad crossing.

Along the APE in between King's Highway Station/Tar Kiln Road and Route I-195, the following properties are National Register eligible. Connected early-twentieth-century brick buildings comprise the Pierce Brothers Textile Mill Complex (Map No. NB.026), manufacturers of fine cotton cloth products, that is located west of the New Bedford Main Line at 1125 County Street. The Gothic Revival-style, wood-frame Christ Presbyterian Church (Map No. NB.029), located approximately 250 feet west of the New Bedford Main Line at 1097 County Street, was constructed circa 1890. The Purchase Street Fire Station (Map No. NB.053) on the west side of the New Bedford Main Line at 2071 Purchase Street is a Renaissance Revival brick building constructed circa 1910.

The area between I-195 and Route 6 includes the following National Register listed properties. The Acushnet Heights Historic District (Map No. NB.C) is a nineteenth century residential neighborhood located west of the rail right-of-way near Acushnet Avenue. The Wamsutta Mills Historic District (Map No. NB.D), comprised of a cotton cloth mill established in 1847 and associated worker housing, is located east and west of the New Bedford Main Line where it crosses Acushnet Avenue. The Union

Street Railway Carbarn (Map No. NB.063) at 1959 Purchase Street in Weld Square, is a Classical Revival style, two-story, brick structure constructed in 1910. The Dawson Building (Map No. NB.065) at 1851 Purchase Street is a Classical Revival style, brick office building with cast-iron storefronts built in 1896. Both are also within the Acushnet Heights Historic District.

The following properties located between I-195 and Route 6 are eligible for National Register listing. The Classical Revival Style, brick New Bedford Textile School (Map No. NB.069) constructed between 1899 and 1911 sits one block west of the New Bedford Main Line at 1213 Purchase Street across John F. Kennedy Highway from the proposed Whale's Tooth Station. The Guardian Angel Parochial Schoolhouse (Map No. NB.064) constructed in 1896 and located 300 feet east of the New Bedford Main Line at 844 Acushnet Avenue is not eligible.

Three traction power sites and one layover facility are proposed in New Bedford as part of the Stoughton Alternatives.

TP-07, Substation (TPSS-2) is located south of Samuel Barnett Boulevard on the New Bedford Main Line, near the existing electrical transmission line. No National Register listed or eligible historic properties have been identified in the APE.

- TP-09, Paralleling Station (PS-6) is located on the New Bedford Main Line within 400 feet of four National Register listed resources: the Acushnet Heights Historic District (Map No. NB.C), Wamsutta Mills Historic District (Map No. NB.D), Union Street Railway Carbarn (Map No. NB.063), and the Dawson Building (Map No. NB.065).

- The Church Street Layover Facility is located on the west side of the New Bedford Main Line rail right-of-way near Church Street. No National Register listed or determined eligible historic properties have been identified in the APE.

- The Wamsutta Street Layover Facility is located on the east side of the New Bedford Main Line rail between Wamsutta Street and the proposed Whale's Tooth Station. The National Register Listed Wamsutta Mill Historic District (Map No. NB.D) and the National Register eligible Revere Copper Products mill (Map No. NB.080) are both located about 400 feet to the north.

Fall River

Approximately 6.5 miles of the Fall River Secondary line rail right-of-way, one traction power site and two stations, Fall River Depot and Battleship Cove, are located in Fall River as part of the Stoughton Alternatives. All of the historic resources in Fall River are situated along the Fall River Secondary rail corridor. The Southern Triangle encompasses seven historic districts and six individual properties included in the Fall River MRA (Map No. FR.C). The boundaries of the Fall River MRA are the city limits. The entire MRA consists of five National Register Historic Districts, 90 properties individually listed in the National Register, and four districts and one individual property determined eligible for National Register listing.

The following properties located between the Freetown town line and Route 79 are listed in the National Register. The William Collins House (Map No. FR.005, FR.C) is Federal style Cape Cod cottage constructed circa 1800 that is approximately 300 feet east of the Fall River Secondary at 3775 North Main Street. The North Christian Congregational Church (Map No. FR.006, FR.C) is a Gothic Revival style

wood-frame building constructed circa 1842 that is located 100 feet west of the Fall River Secondary at 3538 North Main Street. The Borden-Winslow House (Map No. FR.010, FR.C) is a wood-frame, Georgian style house constructed circa 1740 that is located approximately 400 feet east of the Fall River Secondary at 3063 North Main Street. The Squire William B. Canedy House (Map No. FR.012, FR.C) is a wood-frame, Federal style house constructed circa 1806 that is located approximately 100 feet east of the Fall River Secondary at 2634 North Main Street.

The following properties located between the Freetown town line and Route 79 are eligible for National Register listing. The North Main Street Area (Map No. FR.D) is an approximately 1-mile-long residential corridor roughly bounded by the Fall River Secondary to the west. It encompasses a neighborhood developed between the early nineteenth to the early twentieth century. The William J. Wiley Middle School (Map No. FR.013) is a Classical Revival style, steel and concrete building with red brick sheathing and brownstone trim constructed from 1911 to 1912. The school is located approximately 500 feet east of the Fall River Secondary at 2613 North Main Street within the potentially National Register eligible North Main Street Area.

The following properties located between Route 79 and President Avenue are listed in or eligible for listing in the National Register. The Border City Mills (Map No. FR.E, FR.C) are located on both sides of Weaver Street west of the Fall River Secondary and were constructed between 1872 and 1889 adjacent to a railroad spur connecting the Fall River Branch Railroad to a wharf on the Taunton River. The Sagamore Mill Nos. 1 and 3 Complex (Map No. FR.F, FR.C) consists of brick and granite textile mills built between 1888 and 1907, which are located on both sides of Ace Street on the west side of the Fall River Secondary. The Sagamore Mill No. 2 (Map No. FR.G, FR.C) is a five-story granite loft constructed in 1881, located at 1822 North Main Street across the Fall River Secondary right-of-way from the rest of the Sagamore Mills complex. The Foster Spinning Company (Map No. FR.H, FR.C) was constructed in 1916 at 119 Cove Street, west of the Fall River Secondary. The mill was the last new textile manufacturing facility established in Fall River. The Narragansett Mills complex (Map No. FR.J, FR.C) is comprised of nine brick buildings constructed between 1872 and 1895, located at the corner of North Main Street and Narragansett Street, approximately 400 feet east of the Fall River Secondary. The North Burial Ground (Map No. FR.K, FR.C) is a rectangular property bounded by the Fall River Secondary to the west, Brightman Street to the north, North Main Street to the east, and Cory Street to the south. It is the city’s oldest municipal cemetery, established circa 1810 and purchased by the City of Fall River in 1825. The Border City Mill No. 2 (Map No. FR.015, FR.C) is an Italianate style brick mill loft with an exterior stair tower constructed in 1873 for the manufacture of woolens that is located approximately 300 feet west of the Fall River Secondary at 1 Weaver Street. The Weaver Street Bridge (Map No. FR.016) over the Fall River Secondary is a single-span, built-up, riveted steel plate, deck girder structure constructed in 1910 that was previously determined National Register eligible by the SHPO. The bridge was rebuilt in 1960, but is notable for its highly decorative cast-iron railings and battered stone abutments. The Hathaway Brightman House (Map No. FR.026, FR.C) is a wood-frame, Gothic Revival style house constructed circa 1858 that is located approximately 400 feet east of the Fall River Secondary at 205 Crescent Street. The St. Joseph’s Roman Catholic Church Complex (Map No. FR.066, FR.C) is located approximately 800 feet east of the Fall River Secondary at 1355 North Main Street across from the North Burial Ground. The complex consists of a High Victorian Gothic style, brick church and Second Empire style, wood-frame rectory built circa 1880, and a school constructed in 1930.

The following properties located between Route 79 and President Avenue are eligible for National Register listing. The Wellington-Brownell Street Area (Map No. FR.I) is an approximately 0.5-mile-long neighborhood bounded by the Fall River Secondary to the east. The area encompasses a late-

nineteenth- and early-twentieth-century residential neighborhood formerly known as Mechanicsville and is eligible for National Register listing. The 311 Crescent Street House (Map No. FR.017) is a Second Empire style, multi-family, wood-frame residence constructed circa 1880 that is located approximately 400 feet east of the Fall River Secondary in the Border City Mills neighborhood. The St. Michael's Roman Catholic Church (Map No. FR.050) is a Neo-Gothic Revival style brick building constructed in 1896 that is located approximately 250 feet west of the Fall River Secondary at 199 Essex Street. The Cotton Warehouse (Map No. FR.67) located on the west side of the Fall River Secondary at 7 Oregon Street, was constructed of brick pier and spandrel walls with iron interior posts circa 1910.

The St. Matthew's Convent (Map No. FR.052) is a Colonial Revival style brick and concrete building constructed circa 1920 that is located approximately 300 feet west of the Fall River Secondary at 189 Wellington Street. The St. Matthew's School (Map No. FR.053) is a Colonial Revival style brick and concrete building constructed circa 1920 that is located on the west side of the Fall River Secondary at 221 Wellington Street. Based on the results of the intensive survey, the Corps, in consultation with the Massachusetts SHPO has determined these two properties to be ineligible.

The following properties located between President Avenue and Route I-195 are listed in the National Register. The Diners of Massachusetts Multiple Property Submission (Map No. FR.M) encompasses individual diners throughout Massachusetts, including Al Mac's Diner (Map No. FR.070, FR.M), which is located in the APE at 135 President's Avenue, approximately 300 feet west of the Fall River Secondary. Al Mac's is a stainless steel diner opened by Fall River's McDermott Lunch Company in 1954 and moved to its current location in the mid-1970s. The Lafayette-Durfee House (Map No. FR.082) is a wood-frame Georgian style building constructed circa 1747 that is located approximately 400 feet east of the Fall River Secondary. It was moved to its current location at 94 Cherry Street in 1874.

The following properties are located between President Avenue and Route I-195. The Pearce-Durfee Street Area (Map No. FR.L) is a large, 1-mile-long residential area bounded by the Fall River Secondary to the west. The area is defined by early nineteenth-century through the twentieth-century residential buildings that filled in a street grid originally laid out by 1850. The Pearce Durfee Street Area is eligible for listing on the National Register. The 800 Davol Street Inn (Map No. FR.073) is a wood-frame, Second Empire style building constructed circa 1870 that is located approximately 400 feet from the proposed Fall River Depot Station on the Fall River Secondary. The Davol Inn has been determined not eligible for listing on the National Register due to loss of the original historic fabric and replacement with modern materials. The 524 Durfee Street House (Map No. FR.081) is a wood-frame Italianate style house constructed circa 1870 that is located approximately 200 feet east of the Fall River Secondary. The Central Street Bridge over Quequechan River (Map No. FR.084) is located west of the Fall River Secondary, below the I-195 Braga Bridge. It is a single-span stone arch bridge constructed in 1903 in the course of a Fall River railroad grade elimination project and has been determined eligible for listing in the National Register.

The following property located between I-195 and the south terminus of the Fall River Secondary at Battleship Cove Station is listed in the National Register. The American Printing Company–Metacomet Mill (Map No. FR.N, FR.C) is a complex of masonry buildings constructed between 1847 and the early twentieth century along Anawan Street. The portion of the complex to the east of the Fall River Secondary contains the earliest buildings.

The following properties, located between I-195 and the south terminus of the Fall River Secondary at Battleship Cove Station, are eligible for National Register listing. The American Printing Company

Machine Shop (Map No. FR.088) is located approximately 400 feet west of the Fall River Secondary near Battleship Cove Station, at the corner of Anawan and Water streets. The machine shop is a brick mill loft constructed circa 1900 for the neighboring American Printing Company-Metacomet Mill, which is listed in the National Register. The Borden and Remington Company (Map No. FR.089) consists of a brick loft with connected brick structures constructed as a paint mixing factory circa 1890. The mill is located at 105 Anawan Street on the west side of the Fall River Secondary near Battleship Cove Station.

One traction power site is proposed in Fall River as part of the Stoughton Alternatives.

- TP-11, Paralleling Station (PS-05) as part of the Stoughton Alternatives is located in a dense urban area on the Fall River Secondary, near the proposed Fall River Depot Station, across from the National Register-eligible Pearce-Durfee Street Area (FR.L), a neighborhood constructed between 1870 and 1920.

Stations

Three of the proposed stations (Whale's Tooth, Fall River Depot, and Battleship Cove) have at least one historic resource within the APE that is an NHL or is listed in, eligible for the National Register. The proposed Whale's Tooth Station on the New Bedford Main Line is across John F. Kennedy Highway from the National Register-eligible New Bedford Textile School. The proposed Fall River Depot Station on the Fall River Secondary is adjacent to the Pearce-Durfee Street Area which is eligible. The proposed Battleship Cove Station at the terminus of the Fall River Secondary is adjacent to the National Register listed American Printing Company-Metacomet Mill complex, and the National Register- eligible American Printing Company Machine Shop, and Borden and Remington Company. The remaining two proposed stations (Freetown and King's Highway) do not have any historic resources within the APE that are designated as NHLs or listed in, or determined eligible for the National Register.

Two of the proposed stations (Easton Village and Taunton [Dean Street]) have at least one historic resource within the APE that is designated as an NHL, or listed in, previously determined eligible for, or recommended as eligible for the National Register. The proposed Easton Village Station on the Stoughton Line in Easton is located immediately adjacent to the Old Colony Railroad Station (Map No. Ea.003), which is part of a NHL district and is within the North Easton Historic District. The proposed station site abuts important contributing properties of this district that are associated with the Ames Shovel Works. The railroad also contributes to the setting of the district. The proposed Taunton (Dean Street) Station in Taunton is adjacent to the National Register-eligible Taunton Center Area.

The remaining three proposed stations (North Easton, Raynham Park, East Taunton [North]) do not have any historic resources within the APE that are designated as an NHL or listed in, or determined eligible for the National Register.

Two existing stations are historic resources: Canton Junction (Map No. Ca.001) at the junction of the Stoughton Line and Amtrak Northeast Corridor and Stoughton Station (Map No. St.025), which is also within the Downtown Stoughton Area. The third existing station, Canton Center, is not a historic resource but is adjacent to the Canton Center Area.

4.8.2.2 Archaeological Resources

The survey of areas of where archaeological sites may occur was undertaken in two phases. An initial reconnaissance survey was conducted which included the Stoughton Alternatives followed by

supplemental surveys which included the Whittenton Alternatives as well as additional survey information on the Stoughton Alternatives and identified areas of archaeological sensitivity. The second phase of survey was an intensive (locational) survey which was conducted in areas determined as archaeologically sensitive by the prior reconnaissance surveys. The intensive (locational) survey included areas identified as potentially sensitive by PAL and supplemented by additional information provided by the Corps.

This section presents the results of the intensive (locational) survey for the Stoughton and Whittenton Alternatives. Fifteen sensitive areas within the right-of-way and three station locations previously determined to be sensitive were subjected to intensive (locational) survey. The following discussion is organized by project element and sensitive area. The Intensive (Locational) Survey is provided as Appendix 4.8-B.

Stoughton Alternatives

The Stoughton Line portion of the Stoughton Alternatives consists of the Stoughton Line (active and inactive freight and commuter) railroad right-of-way, and five proposed stations (Stoughton, North Easton, Easton Village, Raynham Park, and Taunton Depot). There are also additional project elements that have been identified for this alternative including a new frontage road in Stoughton along the rail right-of-way, a grade separation (tunnel) crossing at Route 138 in Raynham, and a new third track (outside of the right-of-way) associated with the Taunton Depot Station. High sensitivity areas were assessed for the railroad right-of-way in Easton. These consist of an area north of Foundry Street that contains a documented nineteenth-century house lot and the area between Elm Street and the Stoughton town line that contains documented eighteenth- and nineteenth century domestic sites.

As identified during the 2001 survey, the sections of the Stoughton Line right-of-way that run through Hockomock and Pine swamps in Easton and Raynham are raised railroad embankments. The rail embankment traverses areas considered to have a high archaeological sensitivity for pre-contact resources.

Four of the proposed stations (Stoughton, North Easton, Easton Village, and Freetown) were identified as containing moderate and high sensitivity areas for potentially significant pre-contact sites and documented/recorded post-contact resources. The third track at the East Taunton Station was also assessed as having moderate sensitivity for pre-contact sites.

Intensive (Locational) Survey Results—Stoughton & Whittenton Alternatives, Not Including the Southern Triangle

The intensive (locational) archaeological survey resulted in the identification of 16 archaeological sites in Easton, Raynham, Taunton, Freetown, and Fall River, five of which are situated within the Lower Taunton River Basin archaeological district. These sites include two sites located in or near proposed stations, 10 pre-contact period sites within the proposed limit of work for the Stoughton Alternatives right-of-way, and four within the proposed limit of work for the Whittenton Alternatives right-of-way. Each of these 16 newly identified archaeological sites has been assessed for its research value/potential and eligibility for listing in the National Register. The survey also resulted in the identification of low density nineteenth and twentieth century sheet refuse/refuse scatters of cultural materials in two of the proposed station locations and all of the tested right-of-way segments. None of these sheet refuse/refuse scatters are associated with identified sites and none are considered to meet the criteria of eligibility for listing in the National Register.

North Easton Station—The intensive survey identified a low density of post-contact (likely late nineteenth-twentieth century) cultural materials within the sensitive portion of the North Easton Station project area. The materials are interpreted as sheet refuse and together with the stone wall suggest that premodern period agricultural activities took place within the project parcel. However, given the lack of cultural features other than the remnant stone wall, the sheet refuse is not considered to represent an archaeological site and is not eligible for listing in the National Register. No additional archaeological investigations are recommended within the North Easton Station project area.

Easton Village Station—The intensive survey identified railroad-related cultural deposits and fill strata within the sensitive portion of the Easton Village Station project area. The cultural deposits including structural remains and artifact assemblage are designated the Easton Village Railroad Station Site. Structural remains consist of: 1) the concrete piers in MT-04 (present parking lot) belonging to the documented early twentieth-century railroad water tower that was located south of the historic railroad station (extant Easton Historical Society building); and 2) a rectangular stone foundation, investigated in JTP-01 (wooded area), belonging to the documented late nineteenth/early twentieth century railroad shed located on Mechanic Street.

The cultural material assemblage consists exclusively of post-contact cultural materials (structural and domestic items). No structural remains or artifacts relating to documented pre-nineteenth century railroad industrial activities in this area were identified during the intensive survey. No pre-contact period artifacts or features were encountered in the trenches. Undisturbed, natural soils were encountered in only one trench, MT-03, and these intact soils were void of cultural materials. The fill episodes recorded in all of the excavated trenches represent three campaigns of railroad construction: the initial laying of the railroad track by the Dighton & Somerset Railroad Line between Stoughton and North Easton 1855, the Old Colony Railroad Line’s 1866 extension of the track to points south of North Easton, and the installation of an adjacent second track by the Old Colony Railroad in 1888. In each instance, large amounts of fill were required to raise the railroad roadbed to final grade. Photographs of the railroad from the late nineteenth century and early twentieth century illustrate the drastic changes the railroad brought to the landscape of the area. The identified railroad water tower pier remains possess poor physical integrity and the railroad shed foundation possesses fair integrity. The post-contact period artifact assemblage represents sheet refuse related to the railroad and modern period parking lot land uses, and is consistent with the documented mid-nineteenth to mid-twentieth century occupation of the railroad depot at this location. Given the limited complexity of the identified structural remains and artifacts and known period of occupation, they are considered to have a low research potential to provide significant new information relating to the historical record of the mid-nineteenth to mid-twentieth century Easton Village railroad depot and its role in the greater Old Colony Railroad transportation network. The Easton Village Railroad Station Site is therefore recommended as not eligible for listing in the National Register. No additional archaeological investigations within the Easton Village Station project area are recommended.

Freetown Station—The intensive survey identified a low density of post-contact nineteenth- to twentieth century) cultural materials and pre-contact lithic chipping debris within highly disturbed stratigraphic contexts in the Freetown Station project area. Due to the lack of associated features and the disturbed context of the post-contact cultural materials, they are interpreted as refuse scatter manipulated by late-twentieth century earthmoving activities. Given their geographic location within the Lower Taunton River Basin archaeological district and proximity to two known site areas, they are designated the Landowner’s Folly Site. However, the disturbed nature of their contexts and the lack of associated diagnostic artifacts, artifact concentrations, or features preclude their potential to yield

information important to the prehistory of the area. The Landowner's Folly Site is not eligible for listing in the National Register. No further archaeological investigations within the Freetown Station project area are recommended.

Elisha Harvey Gravesite—Preliminary research was conducted for the Captain Elisha Harvey Gravesite located adjacent to the South Coast Rail project railroad right-of-way in Easton, Massachusetts. The preliminary research consisted of collecting available information on the location and historical context of the gravesite. As part of the reseach effort, Mr. Frank Meninno of the Easton Historical Society was contacted for any information that is locally known about the gravesite. No parcel-level documentary (deed) research, contact with the Easton Historical Commission or Cemetery Commission, or field survey was conducted.

The Captain Elisha Harvey Gravesite is located within the YMCA property at 25 Elm Street on the west side of the railroad right-of-way, approximately one block north of the proposed Easton Village Station (Figure 4.8-17). The gravesite is indicated by a single granite marker inscribed as follows: "LOCATION OF CAPT. ELISHA HARVEY CEMETERY 1775." An aluminum post adorned with an American veteran's flag and small plaque that says "CAPT. ELISHA HARVEY 1757" is adjacent to the stone memorial. The monument is situated at the north end of the YMCA Wellness Center parking plot, and the grave's location is believed to have been near the northeast corner of the lot. The town of Easton placed and maintains the stone monument and marker at this location. The gravesite is located on town property, Assessor map U11-Lot 057, and is listed in the Town of Easton's Historic Preservation Plan as having been established in 1775. The Corps, in consultation with the Massachusetts SHPO, has determined that the Elisha Harvey Gravesite is eligible for listing in the National Register. The adjacent railroad right-of-way is at grade at this location on both sides of Elm Street.

There are no individual grave stones and the stone memorial information comes from town records. The gravesite is not included in the MHC inventory of historic and archaeological assets of the Commonwealth. It is physically located within the North Easton Historic District boundaries, although it is not mentioned in the 1972 National Register of Historic Places Inventory-Nomination Form. According to the Town of Easton Cemetery Database (last updated December 11, 2012), the gravesite contains nine burials associated with the Carr, Harvey, Packard, and Simmons families, including Elisha Harvey and his wife. The earliest recorded burial is Elizabeth Simmons in 1759, who was the daughter of Mrs. Eseck Carr and her first husband. The last dated burial is that of Captain Harvey in 1790. No other birth or death dates are known for the other recorded interments.

According to the Bristol County Massachusetts Cemeteries Database, the cemetery was abandoned in the mid-nineteenth century and later became part of the fields on a property owned by E.W. Gilbert "near where his hinge-factory stands."[3] At that time, Chaffin indicates that there was a graveyard containing about 15 graves in the field owned by E.W. Gilbert. According to Chaffin, the graves of Rev. Eseck Carr and his wife were reportedly removed to the Washington Street cemetery by their son when the Gilmore hinge-factory was built on the property. The remains of Capt. Elisha Harvey and his wife were left with others in the field "only a few feet from the northwest corner of the factory." Chaffin indicates that Elizabeth Simmons "died as early as the Revolutionary War," and hers was the first burial in this yard," offering a more recent burial date than that of 1759 recorded in the town's cemetery database.

[3] Chaffin, William L. 1886. History of the Town of Easton, Massachusetts.

No cemetery is indicated at this location on mid-eighteenth through mid-twentieth century town maps of Easton. The 1756 (Cobb) map suggests that the cemetery may have been established on property belonging to John Whitman Jr., or John and Samuel Randall at that time. An 1825 map of Easton depicts the property on the south side of Elm Street near this location as belonging to J. Packard, and containing one dwelling. The railroad was put through North Easton to Oliver Street by 1855 (Easton Branch Railroad), and extended to Weir Junction in Taunton in 1866. The 1855 (Walling) map of Easton shows the railroad, but does not indicate a cemetery or other structures adjacent to the west side of the tracks and Elm Street. The 1871 (Beers) map depicts the vacant property belonging to E.W. Gilmore west of the railroad and south of then-named Stoughton (Elm) Street. By the 1886 (Walker) map, the hinge factory building had been constructed adjacent to the railroad tracks south of Elm Street. The hinge factory was still present at the time of the 1895 (Everts and Richards) map. There is no indication of a cemetery on any of these later nineteenth-century maps, and the reported cemetery location at the northwest corner of the factory was depicted as vacant land. The 1942 (Hayward and Hayward) map of Easton also does not depict a cemetery at this location. According to Mr. Meninno of the Easton Historical Society, the Gilmore hinge factory was owned by the Gilmore family in the 1930s, and later absorbed into the Ames Shovel complex for use as a warehouse. The factory building burned in 1959 and was razed.

According to Mr. Meninno there are no known historical maps or boundaries of the cemetery, except for the description provided by William Chaffin in his 1886 history of the town. It is possible that additional documentary research (including parcel level deed work and interviews with members of the Easton Historical Commission and Easton Cemetery Commission) could provide more definitive historic property boundaries for the cemetery in relation to the railroad right-of-way. This information would be used to assist in the effects analysis for the gravesite and develop a written avoidance and protection plan.

Easton, North of Elm Street—The intensive survey identified a low density of post-contact (late nineteenth-twentieth century) cultural materials and one quartz chipping debris within disturbed railroad right-of-way/rail bed soil strata north of Elm Street in Easton. Due to the lack of associated features and the disturbed context, they are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. The materials are not considered to represent an archaeological site and the Corps, in consultation with Massachusetts SHPO, has determined that they are not eligible for listing in the National Register. No additional archaeological investigations are recommended within the Easton, North of Elm Street right-of-way segment.

The two fieldstone foundations of the previously identified Site EST-HA-25 are situated outside of the right-of-way and beyond the limit of project-related disturbances on private property. Postcontact artifacts recovered from the portion of the project area closest to the site cannot be conclusively associated with it due to the residential nature of the surrounding area and railroad-related soil manipulations. However, since the foundations have not been investigated for their significance and National Register eligibility, and given their close proximity (2 meters [6.5 feet]) to the project right-of-way, they would be protected prior to and during project construction activities through the installation of high visibility fencing to avoid inadvertent disturbances.

Easton, North of Depot Street—The intensive survey identified a low density of post-contact (late nineteenth-twentieth century) cultural materials within disturbed railroad right-of-way/rail bed soil strata north of Depot Street in Easton. Due to the lack of associated features and the disturbed context, they are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. The right-of-way extends through residential areas and is

visited by local residents. Much of the bottle glass recorded in test pits is likely indicative of the unauthorized recreational use of the area rather than evidence of historic occupation. The materials are not considered to represent an archaeological site and the Corps, in consultation with Massachusetts SHPO, has determined that they are not eligible for listing in the National Register. No additional archaeological investigations are recommended within the Easton, North of Depot Street right-of-way segment.

Easton, North of Prospect Street—The intensive survey identified a low density of post-contact (nineteenth-twentieth century) cultural materials within primarily disturbed railroad right-of-way/rail bed soil strata north of Prospect Street in Easton. Due to the lack of associated features and the disturbed context, they are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. The right-of-way is visited by local residents, and most of the bottle glass recovered is likely indicative of the recreational use of the area rather than evidence of historic occupation. The materials are not considered to represent an archaeological site and the Corps, in consultation with Massachusetts SHPO, has determined that they are not eligible for listing in the National Register. No additional archaeological investigations are recommended within the Easton, North of the Prospect Street right-of-way segment.

Easton, North of Foundry Street—The intensive survey identified a low density of post-contact (late nineteenth-twentieth century) cultural materials within disturbed railroad right-of-way/rail bed soil strata north of Foundry Street in Easton. No structural remains or artifacts associated with the nearby nineteenth-century Pool family homestead and workshop were identified within the right-of-way. Due to the lack of associated features and the disturbed context, they are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. The materials are not considered to represent an archaeological site and the Corps, in consultation with Massachusetts SHPO, has determined that they are not eligible for listing in the National Register. No additional archaeological investigations are recommended within the Easton, North of Foundry Street right-of-way segment.

Stoughton Alternatives Right-of-way

The intensive survey identified a low density of post-contact (nineteenth-twentieth century) cultural materials within primarily disturbed railroad right-of-way/rail bed soil strata in the Hockomock Swamp raised railroad embankment. Due to the lack of associated features and the disturbed context of these materials, they are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. The post contact materials are not considered to represent an archaeological site and the Corps, in consultation with Massachusetts SHPO, has determined that they are not eligible for listing in the National Register.

Two pre-contact Native American archaeological sites were identified during the intensive survey, designated the Skunk Trapper Site and the Saws Wood Site. While the intensive survey testing did not identify diagnostic artifacts or cultural features at either site area, the presence of chipping debris and variety of lithic material types (rhyolite, quartz, and argillite) suggests that additional classes of data including diagnostic tools and subsistence-related features and activity areas may be present. The Skunk Trapper Site and Saws Wood Sites therefore have the potential to yield information that is important in the region's precontact period archaeological record, and the Corps, in consultation with the Massachusetts SHPO has determined that they both meet Criterion D of eligibility for listing in the National Register.

The intensive survey identified a low density of post-contact (nineteenth-twentieth century) cultural materials within primarily disturbed railroad right-of-way/rail bed soil strata in the Pine Swamp raised railroad embankment. Due to the lack of associated features and the disturbed context of these materials, they are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. The post-contact materials are not considered to represent an archaeological site and are not eligible for listing in the National Register.

Three additional pre-contact Native American archaeological sites were identified during the intensive survey of the Stoughton right-of-way, designated the King Philip Street Site, the Chickering Road Site, and the East Britannia Street Site. At all three locations, the cultural deposits could extend beyond the limits of the right-of-way. While the intensive survey testing did not identify diagnostic artifacts or cultural features in the site areas, the presence of chipping debris, stone tools, and variety of lithic material types (quartz, argillite) suggests that additional classes of data including diagnostic tools and subsistence-related features and activity areas may be present. The King Philip Street Site, Chickering Road Site, and East Britannia Street Site therefore have the potential to yield information that is important in the region's pre-contact period archaeological record, and the Corps, in consultation with the Massachusetts SHPO and the Wampanoag Tribe of Gay Head (Aquinnah) Tribal Preservation Officer has determined all three sites meet Criterion D of eligibility for listing in the National Register.

Taunton and Mill River Bridge Crossings—The intensive survey identified a low density of post-contact (late eighteenth-nineteenth-twentieth century) cultural materials within primarily disturbed railroad right-of-way/rail bed soil strata in the Taunton and Mill River Bridge crossings portion of the Stoughton Alternatives right-of-way. Due to the lack of associated features and the disturbed context of these materials, they are interpreted as refuse scatter introduced and/or redeposited by nineteenth- and twentieth-century railroad construction and maintenance activities. The materials are not considered to represent an archaeological site and the Corps, in consultation with Massachusetts SHPO, has determined that they are not eligible for listing in the National Register. No additional archaeological investigations are recommended within the Taunton and Mill River Bridge crossings right-of-way segment.

Whittenton Alternatives

The Whittenton Alternatives consist of the Stoughton Line (active and inactive freight and commuter) railroad right-of-way as well as the Whittenton Branch right-of-way and portions of the Attleboro Secondary railroad right-of-way. It has the same stations as the Stoughton Alternatives, except for the Taunton (Dean Street) Station and includes one station exclusively associated with the Whittenton Alternatives: the Dana Street Station. The total right-of-way of the Whittenton Alternatives are the same as that of the Stoughton Alternatives except for the Whittenton Branch (inactive) railroad right-of-way, located west of Taunton and a short section of the Attleboro Secondary (active freight) railroad right-of-way. The Whittenton Alternatives do not include the portion of the Stoughton right-of-way extending through Pine Swamp, east of Taunton. The supplemental cultural resource survey conducted of the Whittenton Alternatives and included in the Whittenton Technical Report identified two areas considered archaeologically sensitive for pre-contact sites.

Whittenton Branch 1—The intensive survey identified a low density of post-contact (nineteenth-twentieth century) cultural materials within primarily disturbed railroad right-of-way/rail bed soil strata in the Whittenton Branch 1 sensitivity area of the Whittenton Alternatives right-of-way. Due to the lack of associated features and the disturbed context of the majority of these materials, they

are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. The post-contact materials are not considered to represent an archaeological site and the Corps, in consultation with the Massachusetts SHPO, has determined that they are not eligible for listing in the National Register.

Three pre-contact Native American archaeological sites were identified during the intensive survey, designated the Mel's Diner Site, the Pine Crest Site, and the ATV Trail Site. The testing at the Mel's Diner Site resulted in the recovery of five quartz chipping debris. The Pine Crest Site is situated to the south of the Mel's Diner Site. While the intensive survey testing did not identify diagnostic artifacts or cultural features in the site areas, the presence of chipping debris and a hammerstone suggests that additional classes of data including diagnostic tools and subsistence-related features and activity areas may be present. The Mel's Diner Site, Pine Crest Site, and ATV Trail Site within the Whittenton Branch right-of-way therefore have the potential to yield information that is important in the region's pre-contact period archaeological record, and the Corps, in consultation with the Massachusetts SHPO and Aquinnah Tribal Historic Preservation Officer (THPO), has determined that all three sites meet Criterion D of eligibility for listing in the National Register.

Whittenton Branch 2—The intensive survey identified a low density of post-contact (nineteenth-twentieth century) cultural materials within primarily disturbed railroad right-of-way/rail bed soil strata in the Whittenton Branch 2 sensitivity area of the Whittenton Alternatives right-of-way. Due to the lack of associated features and the disturbed context of the majority of these materials, they are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. The post-contact materials are not considered to represent an archaeological site and Corps, in consultation with the Massachusetts SHPO, has determined that they are not eligible for listing in the National Register. One pre-contact Native American archaeological site was identified during the intensive survey, designated the Cedar Swamp Site. The Cedar Swamp Site within the Whittenton Branch right-of-way therefore has the potential to yield information that is important in the region's pre-contact period archaeological record, and the Corps, in consultation with the Massachusetts SHPO and Aquinnah THPO, has determined that the three sites meet Criterion D and are eligible for listing in the National Register.

Attleboro Secondary—No archaeologically sensitive areas were identified within the rail right-of way that includes the Attleboro Secondary from Whittenton Junction to Weir Junction. Proposed impacts for track improvements within the rail right-of-way are not anticipated to extend outside previously disturbed soil contexts, with the possible exception of the overhead catenary structure support footings that would be needed within the Attleboro Secondary right-of-way for the electrification option.

Stoughton and Whittenton Alternatives—Southern Triangle

The Southern Triangle consists of the existing Fall River Secondary railroad right-of-way, the existing New Bedford Main Line railroad right-of-way, and five proposed stations: Freetown, Fall River Depot, Battleship Cove, King's Highway, and Whale's Tooth. No archaeologically sensitive areas were identified within the rail rights-of way; however, several sensitive areas were found immediately adjacent to them. One of these areas is located along the Fall River Secondary. The other two areas are located along the New Bedford Main Line. They consist of pre-railroad origin cemeteries where the rail right-of-way appears to have cut through (in the case of Freetown) and/or cut along the historic cemetery properties. Both areas have the potential for unmarked burials in the right-of-way embankments.

The Freetown Station project area is identified as containing moderate and high sensitivity areas for potentially significant pre-contact sites and documented/recorded post-contact resources. The Freetown Station is located within the Lower Taunton River Basin Archaeological District, an area designated by the MHC as being highly sensitive for significant pre-contact and contact period Native American sites. A 1.6-mile section of the Fall River railroad right-of-way also lies within this archaeological district.

The remaining stations (Fall River Depot and Battleship Cove) along the Southern Triangle were assessed as having low sensitivity. This assessment is based primarily on the presence of historic and modern period disturbances that have severely compromised the below-ground soil integrity and potential for any meaningful archaeological contexts to be present.

Third Track at Taunton Depot Station—The intensive survey identified a low density of post-contact (nineteenth-twentieth century) cultural materials within the Third Track at Taunton Depot Station right-of-way segment. The materials identified in the disturbed railroad right-of-way/rail bed soil strata are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. Given the lack of cultural features and the disturbed stratigraphic context, these materials are not considered to represent an archaeological site and the Corps, in consultation with the Massachusetts SHPO, has determined that they are not eligible for listing in the National Register. No additional archaeological investigations are recommended within the Third Track at East Taunton Station right-of-way segment.

Fall River Secondary—Lower Taunton River Basin Archaeological District—The intensive survey identified a low density of post-contact (nineteenth-twentieth century) cultural materials within primarily disturbed railroad right-of-way/rail bed soil strata in the Lower Taunton River Basin Archaeological District section of the Fall River Secondary right-of-way. Due to the lack of associated features and the disturbed context of these materials, they are interpreted as refuse scatter manipulated by nineteenth and twentieth-century railroad construction and maintenance activities. The post-contact materials are not considered to represent an archaeological site and the Corps, in consultation with the Massachusetts SHPO, has determined that they are not eligible for listing in the National Register. Five pre-contact Native American archaeological sites were identified within the Lower Taunton River Basin Archaeological District during the intensive survey. These sites are designated the Quartz Vein Site, the Circling Hawk Site, the Cold Toad Site, the Overlook Site North, and the Overlook Site South.

The Quartz Vein Site is located in close proximity to a previously identified site, which yielded quartz and rhyolite chipping debris and two quartz bifaces and was interpreted as a small temporary camp site focusing on lithic manufacture and/or maintenance. Since the Quartz Vein Site cannot be conclusively associated to the nearby site, the cultural deposits are being treated as a separate site area, though the boundaries are not completely defined. The site is adjacent to a large granitic rock outcrop with a visible quartz vein, just outside the right-of-way to the west.

The Quartz Vein Site is representative of Native American land use during the pre-contact, contact, and/or early historic periods. Given its geographic location within the Lower Taunton River Basin archaeological district and close proximity to several other sites, the Quartz Vein Site within the Fall River Secondary right-of-way has the potential to yield information that is important to the region's pre-contact period archaeological record and the Corps, in consultation with the Massachusetts SHPO, and the Aquinnah THPO, has determined that the site is eligible for listing in the National Register.

The Circling Hawk Site is located within the right-of-way and is within the boundaries for a previously recorded site. The MHC site file indicates that it is a large camp site identified by surface collections containing both Archaic and Woodland period cultural material but a description/list of these items is not included with the site form. The presence of a Narrow Stemmed projectile point indicates a Late Archaic through Early Woodland period (5000–1600 Before Present [B.P.]) occupation. While the intensive survey testing did not identify any cultural features, the variety of lithic material types and a finished tool indicates the presence of multiple lithic workshops on the site. The Circling Hawk Site is representative of Native American land use during the pre-contact, contact, and/or early historic periods. Given its geographic location within the Lower Taunton River Basin archaeological district and within the boundaries of a previously recorded site, the Circling Hawk Site within the Fall River Secondary right-of-way has the potential to yield information that is important to the region's pre-contact period archaeological record and the Corps, in consultation with the Massachusetts SHPO, and the Aquinnah SHPO, has determined that the site is eligible for listing in the National Register.

The Cold Toad Site is within the boundaries for a previously recorded site and is in close proximity to a second previously recorded site. The first site is a multicomponent site dating from the Late Archaic–Late Woodland periods (5000–450 B.P). The second site is a small lithic tool manufacture/maintenance site that contained chipping debris, shell, and bone but no finished tools or diagnostic artifacts. Subsurface testing at the Cold Toad Site recovered pre-contact cultural material including chipping debris (rhyolite, quartz), a rhyolite biface, fire-cracked rock, and an identified feature. The feature contained rhyolite chipping debris and fire-cracked rock and possibly represents a hearth or shallow cooking pit based on the visible profile. The cultural deposits could extend beyond the limits of the right-of-way. Since the Cold Toad Site cannot be conclusively associated with previously recorded sites in the area, the cultural deposits are being treated as a separate site area. The Cold Toad Site is representative of Native American land use during the pre-contact, contact, and/or early historic periods. Given its geographic location within the Lower Taunton River Basin archaeological district and its relationship to the encompassing and nearby sites, the Cold Toad Site has the potential to yield information that is important to the region's pre-contact period archaeological record and the Corps, in consultation with the Massachusetts SHPO and the Aquinnah THPO, has determined that the site is eligible for listing in the National Register.

The Overlook Site North is also within the boundaries for a previously recorded site mentioned above and is in close proximity to two others. One of these sites is identified as a lithic workshop and shell/trash midden dating to the Late Archaic Period (5000–3000 B.P.). Materials recovered from this site include a high density of chipping debris, lithic cores, stone tool bifaces, a scraper, and a hammerstone. Two diagnostic projectile points, an Atlantic-like broad dating to the Late or Transitional Archaic period (5000–2500 B.P.) and a Small Stemmed projectile point that dates from the Late Archaic through Woodland periods (5000–450 B.P.). Since the Overlook Site North cannot be conclusively associated to any known sites, the cultural deposits are being treated as a separate site area. The presence of aboriginal pottery indicates a Woodland period (3000–450 B.P.) occupation; however, the piece recovered was too small to refine the date further.

It is possible the shell deposit noted at the Overlook Site North is related to post-contact agricultural practice; however additional testing and/or dating of the shell would be required to make a determination. The Overlook Site North is representative of Native American land use during the pre-contact, contact, and/or early historic periods. Given its geographic location within the Lower Taunton River Basin archaeological district and its relationship to the encompassing and nearby sites the Overlook Site North has the potential to yield information that is important to the region's pre-contact

period archaeological record and the Corps, in consultation with the Massachusetts SHPO and the Aquinnah THPO, has determined that the site is eligible for listing in the National Register.

The Overlook Site South is situated within the boundaries for a previously recorded site and is in close proximity to a second. Since the Overlook Site South cannot be conclusively associated to the previously known sites, the cultural deposits are being treated as a separate site area. The Overlook Site South is representative of Native American land use during the pre-contact, contact, and/or early historic periods. Given its geographic location within the Lower Taunton River Basin archaeological district and its relationship to the encompassing and nearby sites, the Overlook Site South has the potential to yield information that is important to the region's pre-contact period archaeological record and the Corps, in consultation with the Massachusetts SHPO and the Aquinnah THPO, has determined that the site is eligible for listing in the National Register.

New Bedford Main Line—Braley Cemetery—The intensive survey included deed and documentary research for the historic Braley Cemetery located in Freetown between East Chipaway Road and the Freetown-Dartmouth/New Bedford town line (Figure 4.8-12). The research was conducted at the request of the Corps to fully demarcate both the historical and modern boundaries of the cemetery on each side of the contemporary rail right-of-way. The research involved close coordination with the Freetown Cemetery Commission to ascertain the modern boundaries of the cemetery, which consists of three individual lots, two under presumed Town jurisdiction and one privately owned. The historical boundaries in relation to the railroad right-of-way and surrounding parcels are less clearly defined and more research into town meeting and church records may provide additional information. Land evidence and town/cemetery commission records indicate that the oldest part of the Braley Cemetery was in existence prior to the construction of the railroad line in 1839-1840. A number of graves are present within 15 feet of the cut stone retaining wall along the right-of-way embankment, and it is considered possible that graves pre-dating the construction of the railroad were present in the strip of land included in the present-day New Bedford Main Line right-of-way. Presumably any such graves would have been moved by the families at the time of the transfer of property to the railroad company (1840, 1879), particularly since the right-of-way was constructed in a cut embankment. The Braley Cemetery (MHC #FRE.823) is not eligible for listing in the National Register, though steps would be taken to avoid disturbance to any marked and/or unmarked interments during construction.

Layover Facilities

The proposed Wamsutta layover facility in New Bedford was assessed as having high archaeological sensitivity for pre-contact/contact Native American habitation and resource procurement/processing sites and post-contact euro-american domestic, commercial/wharves, and railroad-related structures and cultural deposits below the clean fill-geotextile composition cap. The proposed Weaver's Cove West layover facility in Fall River was previously surveyed for the proposed Weaver's Cove LNG terminal and was assessed as archaeologically non-sensitive.

Additional Work Areas

Areas that possess a moderate sensitivity to project-related disturbances, such as from overhead catenary structures would extend beneath railroad fill and thus, potentially require intensive survey.

The survey would consist of additional background research, including review of soil borings data if and when available, along with subsurface testing in areas of current (or refined) moderate and high

sensitivity. The amount and type of subsurface testing would need to be determined for each archaeologically sensitive area where project impacts are planned.

Avoidance zones would be delineated on project maps for the sensitive off right-of-way work areas identified in Lakeville, Freetown and Easton where there are two pre-railroad cemeteries, and an historical archaeological site of unknown age lying just outside the right-of-way. Protection measures should be implemented during and after construction along the right-of-way property lines in these areas. These measures could consist of high visibility barriers (i.e., orange construction fencing) and staked hay bales put in place prior to construction work to ensure that soils containing important archaeological deposits and marked/unmarked graves are not inadvertently disturbed during clearing and excavation activities.

Recommendations for Surveyed Areas

No further archaeological investigations are recommended for the Stoughton and Whittenton Alternatives rail right-of-ways where project improvements are not anticipated to extend outside previously disturbed soil contexts resulting from construction, maintenance/improvements, and ongoing rail operations. These disturbed right-of-way areas include fill materials, ballast, ties, and rails.

Additional reconnaissance survey for overhead catenary structure support footings within railroad right-of-ways may also be needed to determine the potential for archaeologically sensitive strata below rail bed fill. This additional survey would consist primarily of a review of detailed soil profiles for the project right-of-ways based on soil borings when available. Intensive survey would be conducted in identified sensitive areas where support footings would extend below the rail bed disturbance/fill deposits.

Outstanding Work Areas

There are a number of potential work areas for the Stoughton and Whittenton Alternatives within the South Coast Rail APE that have not yet been subjected to an Intensive (locational) survey. The completion of these surveys would be undertaken when the design aspects of these project elements have been identified at a level sufficient for survey. The elements are addressed in the PA for the project; for the draft PA, see Appendix 4.8-A.

For both the Whittenton and Stoughton Diesel Alternatives this includes the following project elements:

- Portions of the proposed Stoughton Station proposed Dana Street Station
- Grade crossing/road intersection modifications, particularly where existing driveways would be relocated and other ground disturbances are planned outside of existing rail and road rights-of-way
- Temporary and permanent construction easements and property takings off right-of-way along the railroad corridors including utilities work, staging, and construction access roads

For the Whittenton and Stoughton Electric Alternatives, all of the above listed project elements in addition to:

- Electrification facilities (substations, switching stations, paralleling stations and associated access roads) along the Stoughton Line, Whittenton Branch, Attleboro Secondary, Fall River Secondary, and New Bedford Main Line railroad right-of-ways

In summary, a number of known post-contact sites have been identified as described above, and the Corps, in consultation with the Massachusetts SHPO has determined pursuant to 36 CFR 800 et seq. and Appendix C to 33 CFR 325 which of the sites are eligible for inclusion in the National Register. Descriptions of these areas are provided above. The Corps has also identified pre-contact Native American sites and determined that they are likewise eligible for the National Register. The Corps has obtained the concurrence from the Massachusetts SHPO on the eligibility of identified sites for listing in the National Register.

4.8.3 Analysis of Impacts

The following section identifies the potential direct and indirect, as well as the permanent and temporary construction impacts to historic and archaeological resources from implementation of the South Coast Rail project for each element of the alternatives as defined in Chapter 3, *Alternatives*. The potential impacts along the railroad and highway alignments, including traction power facilities for rail electrification, are described in Sections 4.8.3.1 through 4.8.3.5; the potential impacts at the station locations are described in Section 4.8.3.6; and the potential impacts at layover facilities are described in Section 4.8.3.7. Figure 1.4-1 shows the alternative alignments and existing and proposed stations. For each alternative and segment or element of alternative (e.g. station), direct, impacts on historic resources are discussed first, followed by the discussion of archaeological impacts for that alternative segment, or element. Impact analyses are based on the intensive level cultural resources identification completed to date. Specific project elements where additional reconnaissance survey work is anticipated are discussed below. Any additional Intensive-level surveys will be completed prior when more detailed design information is available, and are described in the PA (Appendix 4.8-A).

The effects analysis assessed the potential effects to historic properties based on two types of impacts: 1) direct, or physical impacts to a property; and 2) indirect noise impacts and indirect visual impacts caused by changes in the setting of a historic property or district or a cumulative increase in noise that will result from the project. Indirect noise impacts were classified as Train Noise generated by the operation of trains travelling on rails, Horn Noise generated by warning horn sounding, typically at grade crossings and ranked as Moderate, the potential to cause noticeably increased noise levels and Severe, the potential to cause a significant increase in noise. In many cases, these noise levels were classified as Moderate to Severe. Indirect visual impacts were classified as Minimal, Moderate, or Severe. Additional information regarding the effects analysis can be found in Appendix 4.8-B.

Figures 4.8-2 through 4.8-16 depict the locations of historic resources by alternatives. Appendix 4.8-B presents lists of historic resources and project impacts by alternatives with summaries of alternatives, stations, and layovers.

4.8.3.1 Stoughton Electric Alternative

The Stoughton Electric Alternative alignment would provide commuter rail service from Fall River and New Bedford to South Station through Stoughton, connecting to the existing Stoughton Line and an out-of-service railroad bed. This alternative would use the Northeast Corridor from South Station to Canton Junction. From Canton Junction, the existing Stoughton line would be used to the Stoughton Station.

From there, commuter rail service would be extended, reconstructing a railroad on the out-of-service railroad bed, south through Raynham Junction to Weir Junction in Taunton.

This alignment joins the New Bedford Main Line at Weir Junction, the northern end of the Southern Triangle. Existing commuter rail track would be upgraded to a double track, for the 7.26 miles from Canton Junction to just south of the proposed North Easton station. The remainder of the line south to Weir Junction would be single track, with a 1.19-mile-long double track section in Raynham, a 0.56-mile-long double track section in Taunton, and a 0.44-mile double track section approaching Weir Junction. Infrastructure improvements also include constructing, reconstructing, or widening 43 bridges. New catenary supports, wires, and a new traction power system would be constructed along the length of the line. In addition, three traction power facilities also would be constructed. These are:

- TP-05, Paralleling Station (PS-2) in Taunton
- TP-04, 115 KV Substation (TPSS-1) in Easton
- TP-02, Switching Station (SWS-1) in Canton

One existing train stations would be reconstructed (Canton Center) along the active Stoughton line segment and five new train stations would be constructed (Stoughton, North Easton, Easton Village, Raynham Park, and Downtown Taunton) in the inactive segment. No new layover facilities would be constructed.

A frontage road would be constructed in Stoughton to eliminate grade crossings, and a new grade separation would be constructed at Route 138 in Raynham. A 1.6-mile-long trestle section would be constructed in Raynham and Easton through the Hockomock Swamp.

A cultural resources intensive survey was conducted for the Stoughton Electric Alternative elements and impacts to identified resources are presented below. This section focuses on the existing and extended Stoughton line segment from Canton Junction to Weir Junction.

Historic Resources

The impacts to historic resources along the Stoughton Line segment of the Stoughton Electric Alternative may be permanent or temporary, direct or indirect. A total of 30 historic properties located within the Stoughton Line APE may be affected by the project. Figures 4.8-2 to 4.8-6 show the location of historic resources along the Stoughton Line. Appendix 4.8-B presents the potential impacts to historic resources for the Stoughton Electric Alternative.

Direct Impacts

Direct impacts for the Stoughton Line electric option would be similar to the other project electric alternatives.

The 2,000 feet of the Stoughton Line: Dighton and Somerset/Old Colony Railroad, Fall River Line Railroad Corridor (Map No. Ea.A; Figure 4.8-4) right-of-way that extends through the existing North Easton National Register Historic District will be affected by rebuilding of the rail bed, track, and equipment. This rail segment has been determined as contributing to setting of the district. The proposed changes will alter the physical appearance of the rail right-of-way, including rebuilding the Main Street Bridge.

The alterations would have an adverse effect on the physical properties of both the Stoughton Line segment and the North Easton National Register Historic District.

There will be no direct impacts to historic resources from work at grade crossings or at the three traction power facilities (listed above).

Indirect Impacts

Indirect impacts from the Stoughton Line electric option would be similar to the other electric alternatives. Clearing 60 to 100 feet of vegetation along the right-of-way and grading along the abandoned section of the Stoughton Line south of Stoughton Station would increase right-of-way visibility and affect the setting of historic resources.

The changes to infrastructure and the introduction of new structures along the Stoughton Line would have indirect visual effects on the H.H. Richardson Historic District (Map No. Ea.D, Figure 4.8-4) and the North Easton Historic District (Map No. Ea.B, Figure 4.8-4).

The H.H. Richardson Historic District of North Easton is a discontiguous NHL district consisting of five properties. These properties are the Oliver Ames Free Library (1877), Oakes Ames Memorial Hall (1879), Ames Gate Lodge (1880) and Ames Gardener's Cottage (1884) at Langwater, and the Old Colony Railroad Station (1881), currently owned by the North Easton Historical Society. Of this grouping, the Oliver Ames Free Library and the Oakes Ames Memorial Hall are approximately 400 feet west of the proposed Easton Village Station and the Old Colony Railroad Station is located immediately north of the proposed station abutting the rail right-of-way. The other two properties are well outside of the project APE (see PAL 2009: Volume 5, pg. 14). The proposed changes to the Stoughton Line and the introduction of a new station will affect the visual setting of the three historic properties closest to the project through the introduction of new elements. Adverse effects to National Historic Landmarks require special considerations to avoid, minimize, or mitigate adverse effects and options for mitigating visual impact through color or landscaping are recommended.

The North Easton Historic District (Map No. Ea.B) encompasses the Stoughton Line between Main and Elm streets and the proposed Easton Village Station site. The district includes the Ames Company Shovel Shop complex located adjacent to the proposed Easton Village Station. The Stoughton Line right-of-way (Map No. Ea.A) track structure—including bridges, cuts and fills, retaining walls, and signal infrastructure—is recommended as important to the setting of this district. The changes to the Stoughton Line will alter the appearance of the Stoughton Line: Dighton and Somerset/Old Colony Line segment as noted above. Construction of a new station platform, access and drop off area will occur adjacent to the North Easton Station and Ames Shovel Shop. The design of these changes will introduce new modern rail elements that will have a visual adverse effect.

The introduction of additional rail service will result in increased noise during operations from train noise and horn blowing at grade crossings that will cause moderate to severe noise, or severe at residential, contemplative, and quiet setting historic resources. The sound intrusions may be mitigated through the use of sound insulation or barrier mitigation. In addition to the potential for noise impacts, one historic resource would be affected by the introduction of modern power structures (from a traction power station) that will alter its historic setting. The grade crossings and traction power station facility and the historic properties and areas that would be affected are listed below.

- Washington Street grade crossing: Washington Street Commercial and Institutional District, Canton (Map No. Ca.C; Figure 4.8-2)
- School Street, Porter Street, and Wyman Street grade crossings: Downtown Stoughton Area, Stoughton (Map No. St.B; Figure 4.8-3)
- Oliver Street and Elm Street grade crossings: North Easton Historic District, Easton (Map No. Ea.B, Figure 4.8-4)
- Elm Street grade crossing: Holmes-Linden Street Area, Easton (Map No. Ea.C, Figure 4.8-4);
- Reynolds Street grade crossing: Center Street Area, Easton (Map No. Ea.E, Figure 4.8-4);
- Short Street and Depot Street grade crossings: Easton Center Area, Easton (Map No. Ea.F; Figure 4.8-4);
- Foundry Street grade crossing: Hayward-Pool Area, Easton (Map No. Ea.G, Figure 4.8-5);
- Carver Street grade crossing: Carver Street, Broadway, Raynham (Route 138) (Map No. Ra.B, Figure 4.8-6)
- Britton Street grade crossing: Broadway-Center Street Area, Raynham (Map No. Ra.C, Figure 4.8-6);
- West Brittania Street grade crossing: Dog Kennel and Track, Raynham (Map No. Ra.011, Figure 4.8-6);
- Dean Street grade crossing (Figure 4.8-6):
    - Taunton Center Area, Taunton (Map No. Ta.B)
    - William Woodward House, Taunton (Map No. Ta.020, Ta.C)

* MPS: Multiple Property Submission

Archaeological Resources

The Stoughton Electric APE includes the existing and abandoned railroad right-of-way, the proposed frontage road in Stoughton, the new grade separation at Broadway Street (Route 138) in Raynham, and

any other work areas including electrification infrastructure that would involve earthmoving outside of the previously disturbed railroad right-of-way.

Intensive (Locational) survey completed for the Stoughton Alternative identified 14 archaeological sites. The Corps, in consultation with the Massachusetts SHPO and the Wampanoag Tribe of Gay Head, have determined that 10 of the 14 sites are eligible for listing in the National Register. The following discussion begins with the Stoughton Line segment of the alternative. The archaeological sites identified during the Intensive (locational) Survey for the Stoughton Line portion are presented in Table 4.8-5. The proposed grade separation at the Broadway Street (Route 138) crossing is assessed as having a moderate sensitivity for pre-contact Native American and under-documented post-contact EuroAmerican archaeological sites. An intensive (locational) archaeological survey is needed to identify archaeological sites. Project impacts will be assessed once the intensive survey is completed and when more detailed design information is available. The Corps is developing a PA to ensure that all eligible historic properties are identified and addressed as site designs and/or construction plans progress. The draft PA is attached to this document as Appendix 4.8-A.

Table 4.8-5 Archaeological Sites Identified for the Stoughton Line Segment

Site Name	Identified Cultural Deposits	Preliminary (Approximate) Site Boundaries	NR Eligibility/ Recommendation	Project Alternative
Easton Village Station Railroad Site	Mid-19th-mid-20th c. railroad depot water tower and shed remains and artifact assemblage	Within proposed station footprint: 25-x-125 m (3125 sq. m)	Not NR eligible (low research value)	Stoughton and Whittenton Alternatives
Skunk Trapper Site	11 chipping debris	Within proposed substation footprint: 45-x-80 m (3600 sq. m)	NR eligible	Stoughton and Whittenton Alternatives
Saws Wood Site	4 chipping debris	Within right-of-way: 10-x-20 m (200 sq. m)	NR eligible	Stoughton and Whittenton Alternatives
King Philip Street	1 chipping debris and 1 projectile point tip	Within right-of-way: 10-x-20 m (200 sq. m)	NR eligible	Stoughton Alternatives
Chickering Road Site	39 chipping debris and 1 cobble cortex fragment	Within right-of-way: 10-x-20 m (200 sq. m)	NR eligible	Stoughton Alternatives
East Britannia Street Site	22 chipping debris and 1 quartz scraper	Within right-of-way: 10-x-20 m (200 sq. m)	NR eligible	Stoughton Alternatives

The proposed frontage road in Stoughton along the Stoughton line right-of-way is assessed as having low archaeological sensitivity. No impacts to archaeological sites are identified for this work element.

There is the possibility that proposed overhead catenary structure support footings and deep pile foundations for the proposed trestle in the Hockomock Swamp could extend into archaeologically sensitive strata below rail bed disturbance and fill deposits. Specific sensitivity areas would be determined based on a review of soil borings and/or a detailed soil profile of the right-of-way using soil boring logs.

An intensive (locational) survey was conducted and resulted in the location of five archaeological sites which are eligible for the National Register. Additionally, four historic refuse deposits were identified but are not considered archaeological sites. This alternative would have no effect on these refuse deposits, but may affect the pre-contact archaeological sites.

The archaeological survey has not yet been conducted for track improvements including electrification infrastructure that would involve earthmoving outside of the previously disturbed railroad right-of-way within the APE. Project impacts to archaeological resources in these portions of the Stoughton Electric APE will be assessed when more detailed design information is available, as defined in the PA (Appendix 4.8-A).

Appendix 4.8-C presents the results of the archaeological survey within the Stoughton Line portion of the APE.

4.8.3.2 Stoughton Diesel Alternative

The Stoughton Diesel Alternative is identical to the Stoughton Electric Alternative with the exception of the electrical infrastructure including the substations and the overhead catenary system that are not required for the diesel-powered train service.

Cultural resources surveys were conducted for the Stoughton Diesel Alternative elements and impacts to identified resources are presented below.

Historic Resources

The impacts to historic resources along the Stoughton Line segment of the Stoughton Diesel Alternative may be permanent or temporary, direct or indirect. A total of 26 historic properties (located within the Stoughton Line APE may be affected by the project. Figures 4.8-2 to 4.8-6 show the location of historic resources along the Stoughton Line. Appendix 4.8-B, presents the potential impacts to historic resources for the Stoughton Diesel Alternative.

Direct Impacts

Direct impacts for the Stoughton Line segment of the Stoughton Diesel Alternative are identical to the electric option though the electrical infrastructure is not involved.

Indirect Impacts

Indirect impacts for the Stoughton Line segment of the Stoughton Diesel Alternative are similar to the electric option, with the exception of any impacts from the electrical power infrastructure. Therefore, the diesel option would result in less visual impact.

Table 4.8-6 summarizes the adverse effects likely to result from reconstructing the Stoughton Diesel Alternative.

Table 4.8-6 Potential Adverse Effects to Historic Resources, Stoughton Line Diesel Alternative

Ta.029, Ta.B, Ta.C	Taunton	Neck of Land Cemetery	No	Yes: Moderate to severe horn noise	No	Noise

Archaeological Resources

The effects to archaeological resources for the Stoughton Diesel Alternative will be the same as for the Stoughton Electric Alternative with the exception of any impacts from the electrical power infrastructure.

4.8.3.3 Whittenton Alternatives

The Whittenton Electric Alternative is a variant of the Stoughton Electric Alternative alignment described in Section 4.8.3.1. At Raynham Junction, the line would divert to the southwest, following the old, unused Whittenton Branch railroad line. This alignment would connect with the Attleboro Secondary near the Whittenton neighborhood in Taunton then continue on toward the southeast to connect with the New Bedford Main Line at Weir Junction.

This alternative would consist of 3.48 miles of single track on the Whittenton Branch, 1.62 miles of single track on the Attleboro Secondary, and 0.62 mile of double track on the Attleboro Secondary west of Weir Junction. New grade crossings would be built and equipment installed. New catenary supports, wires, and a new traction power system would be constructed along the length of the line. Stations along the Stoughton Line portion of this alternative are the same as Stoughton Alternatives, except for Taunton Station. No traction power facilities, new stations, or layover facilities would be constructed within the Whittenton Branch corridor.

The results of the cultural resources intensive surveys for the Whittenton Electric Alternative elements, and impacts to identified resources are presented below. This section discusses first the Whittenton Branch right-of-way, followed by the Attleboro Secondary right-of-way.

Whittenton Branch Right-of-way of the Whittenton Electric Alternative

Historic Resources

The impacts to historic resources along the Whittenton Branch segment of the Whittenton Electric Alternative of the project may be permanent or temporary, direct or indirect (Table 4.8-7). A total of 4 historic districts located within the Whittenton Branch Line APE may be affected by the project's electric option. Figures 4.8-7 and 4.8.8 show the location of historic resources along the Whittenton Branch Line. Appendix 4.8-B presents the potential impacts to historic resources for the Whittenton Branch of the Whittenton Electric Alternative. North of the Whittenton Branch and Raynham Junction, the Whittenton Electric Alternative may affect the properties located on the Stoughton Line as described above, in addition to the properties of the Southern Triangle described below.

Table 4.8-7 Potential Adverse Effects to Historic Resources, Attleboro Secondary and Whittenton Branch, Whittenton Electric Alternative

Ta.309, Ta.C	Taunton	William Lawrence House	No	Yes: Moderate horn noise	Yes: Moderate, in vicinity of new catenary	Visual

Direct Impacts

Direct impacts for the Whittenton Branch electric option will be similar to the other electric alternatives, but will include clearing and grading and construction of new track and grade crossings along the abandoned line.

There will be no direct impacts to historic resources for new grade crossings work within the right-of-way, and no traction power facilities are proposed.

Indirect Impacts

Indirect impacts from the Whittenton Electric Alternative would be similar to the Stoughton Electric Alternative, but would also involve clearing that would increase the visibility of the newly reactivated right-of-way from nearby historic properties. The abandoned right-of-way crosses or is adjacent to five historic districts.

Train operations and horn blowing will result in moderate to severe, or severe noise that may require noise barrier or sound insulation at the following historic resources:

- Dean and Whittenton Streets grade crossings: Taunton MRA (Map No. Ta.C, Figure 4.8-8)
- Whittenton Street grade crossing (Figure 4.8-7):
  - Whittenton Mill Area (Map No. Ta.F)
  - Reed and Barton Worker Housing (Map No. Ta.H)
- Warren Street grade crossing: Ancient Whittenton Area (Map No. Ta.I, Figure 4.8-7).

Archaeological Resources

The Whittenton Electric APE includes the abandoned railroad right-of-way and any other work areas including electrification infrastructure that would involve earthmoving outside of the former railroad right-of-way. Table 4.8-8 presents the archaeological sites identified for Whittenton Branch and Attleboro Secondary segments of the Whittenton Alternatives.

Four archaeological sites are located within the Whittenton Electric former right-of-way portion of the APE along the Whittenton Branch alignment. The four sites have been determined by the Corps, in consultation with the Massachusetts SHPO and the Aquinnah THPO, to be eligible for the National Register. Project impacts to archaeological resources in the Whittenton Electric APE will be assessed when more detailed design information is available.

Table 4.8-8 Archaeological Sites identified for the Whittenton Branch Rail Segment

Site Name	Identified Cultural Deposits	Preliminary (Approximate) Site Boundaries	NR eligibility/ recommendation	Project Alternative
Mel's Diner Site	5 chipping debris	Within right-of-way: 10-x-10 m (100 sq. m)	NR eligible	Whittenton Alternative
Pine Crest Site	1 chipping debris	Within right-of-way: 10-x-20 m (200 sq. m)	NR eligible	Whittenton Alternative
ATV Trail Site	1 chipping debris and 1 hammerstone	Within right-of-way: 10-x-10 m (100 sq. m)	NR eligible	Whittenton Alternative
Cedar Swamp Site	35 chipping debris, fire-cracked rock, fire pit feature	Within right-of-way: 27-x-30 m (810 sq. m)	NR eligible	Whittenton Alternative

Attleboro Secondary Right-of-way of the Whittenton Electric Alternative

Existing freight track within the Attleboro Secondary would be upgraded and the line would be single track between the Whittenton Junction and Taunton, with the remaining 0.62 mile to Weir Junction being double track. New catenary supports, wires, and a traction power system would be constructed along the length of the line. One new train station would be constructed in Taunton (Dana Street Station). No new layover facilities would be constructed along this alternative segment.

Historic Resources

The impacts to historic resources along the Attleboro Secondary segment of the Whittenton Electric Alternative may be permanent or temporary, direct or indirect. A total of 15 historic properties located within the Attleboro Secondary APE may be affected by the project. Figures 4.8-8 to 4.8-9 show the location of historic resources along the Attleboro Secondary.

Direct Impacts

Direct impacts for the Attleboro Secondary electric option will be similar to the other project electric alternatives (discussed above).

The construction of the Attleboro Secondary segment of the Whittenton Electric Alternative will occur within the right-of-way. Both paralleling stations (listed above) would be constructed within existing right-of-way as well. There are no historic resources located within these construction areas. Therefore, there are no permanent direct impacts of the project on historic resources within the Attleboro Secondary APE.

Indirect Impacts

Indirect impacts for the Attleboro Secondary electric option will be similar to the other project electric alternatives described above.

The introduction of additional rail service will result in increased noise during operations from train noise and horn blowing at grade crossings. The noise increase will cause moderate to severe or severe noise at residential, contemplative, and quiet setting historic resources at the following grade crossing locations. These specific areas and resources would likely require sound insulation or barrier mitigation:

- Weir Street and Bow Street grade crossings: High Street Area, Taunton (Map No. Ta.D; Figure 4.8-8)
- Danforth Street grade crossing (Figure 4.8-8):
    - Massachusetts State Hospitals and State Schools, Taunton (Map No. Ta.R)
    - Taunton State Hospital Historic District, Taunton (Map No. Ta.S)
- Tremont Street grade crossing (Figure 4.8-8):
    - Tremont Street Area, Taunton (Map No. Ta.T)
    - Hodges Avenue Area, Taunton (Map No. Ta.U)
- Winthrop Street and Webster Street grade crossings: Harrison Street Area, Taunton (Map No. Ta.V, Ta.D; Figure 4.8-8)
- Porter Street and Cohannet Street grade crossings (Figure 4.8-8):
    - St. Thomas Episcopal Church, Taunton (Map No. Ta.208, Ta.C)
    - Henry G. Brownell House, Taunton (Elks Lodge No. 150) (Map No. Ta.211, Ta.C)
- Winthrop Street, Porter Street, and Cohannet Street grade crossings (Figure 4.8-8):
    - Lord-Baylies-Bennett House, Taunton (Taunton Masonic Lodge) (Map No. Ta.245, Ta.C)
    - Samuel Washburn House, Taunton (Map No. Ta.246, Ta.C)
- Winthrop Street and Cohannet Street grade crossings: Samuel Colby House, Taunton (Map No. Ta.254, Ta.C; Figure 4.8-8)
- Winthrop Street grade crossings: J.C. Bartlett House, Taunton (Map No. Ta.266, Ta.C; Figure 4.8-8)
- Barnum Street and Weir Street grade crossings: William Lawrence House, Taunton (Map No. Ta.309,Ta.C; Figure 4.8-8)

TP-21, paralleling station (PS-2) in Taunton (Figure 4.8-8) may cause adverse visual effects to four adjacent historic properties through the introduction of modern power structures that alter the historic setting:

- Henry G. Brownell House (Map No. Ta.211)

- McKinstrey House (Map No. Ta.209)
- Rhodes Button Company (Map No. Ta.225); and Thomas Episcopal Church (Map No. Ta.208)

Table 4.8-9 summarizes the adverse effects likely to result from reconstructing the Attleboro Secondary segment of the Whittenton Electric Alternative.

Archaeological Resources

The Attleboro Secondary segment of the APE includes active freight right-of-way from the Attleboro Bypass and Weir Junction in Taunton. There are no recorded archaeological sites or sensitive areas within the previously disturbed Attleboro Secondary railroad right-of-way.

There is the possibility that proposed overhead catenary structure support footings could extend into archaeologically sensitive strata below rail bed disturbance and fill deposits. Specific sensitivity areas would be determined based on a review of soil borings and/or a detailed soil profile of the right-of-way using soil boring logs. An intensive (locational) survey may be needed in sensitive areas where direct physical construction impacts are planned. Project impacts to archaeological resources will be assessed when more detailed design information is available, as described in the draft PA (Appendix 4.8-A)

The archaeological survey has not yet been conducted for track improvements including electrification infrastructure that would involve earthmoving outside of the railroad right-of-way within the APE. Project impacts to archaeological resources in these portions of the Attleboro Secondary Electric APE will be assessed when more design information is available.

4.8.3.4 Whittenton Diesel Alternative

The Whittenton Diesel Alternative is identical to the Whittenton Electric Alternative with the exception of the electrical infrastructure including the overhead catenary system that is not required for the diesel-powered train service.

A historic resources survey was completed for the Whittenton Diesel Alternative and impacts to identified historic resources are presented below. This section discusses first the Whittenton Branch right-of-way segment of the Whittenton Alternative, followed by the Attleboro Secondary right-of-way segment.

Whittenton Branch Right-of-way of the Whittenton Diesel Alternative

Historic Resources

The impacts to historic resources along the Whittenton Branch segment of the Whittenton Diesel Alternative of the project may be permanent or temporary, direct or indirect. A total of 7 historic properties (1 individual and 6 historic districts) located within the Whittenton Branch Line APE may be affected by the alternative's diesel option. Figures 4.8-7 to 4.8-8 show the location of historic resources along the Whittenton Branch. Appendix 4.8-B, presents the potential impacts to historic resources for the Whittenton Diesel Alternative.

The Whittenton Diesel Alternative may affect an additional 21 properties (8 individual properties and 13 historic districts), located on the Stoughton Line north of Raynham Junction. The impacts to these properties are the same as those described in Section 4.8.3.3 above, excluding impacts pertaining to the Taunton Depot, TP-05, Paralleling Station (PS-2), and 7 historic properties located on the Stoughton Line south of Raynham Junction in Raynham and Taunton.

Direct Impacts

Direct impacts for the Whittenton Branch segment of the Whittenton Diesel Alternative are identical to the electric option.

Indirect Impacts

Indirect impacts for the Whittenton Branch segment of the Whittenton Diesel Alternative are similar to the electric option with the exception of any impacts from the electrical power infrastructure. Therefore, the diesel option will result in less visual impact.

Archaeological Resources

See discussion above for the Whittenton Branch right-of-way segment of the Whittenton Electric Alternative.

Attleboro Secondary Right-of-way of the Whittenton Diesel Alternative

Existing freight track would be upgraded and the line would be single track between the Whittenton Junction and Taunton, with the remaining 0.62 mile to Weir Junction being double track.

One new train station would be constructed in Taunton (Dana Street Station). No new layover facilities would be constructed along this alternative segment.

Historic Resources

The impacts to historic resources along the Attleboro Secondary segment of the Whittenton Diesel Alternative may be permanent or temporary, direct or indirect. A total of 28 historic properties (17 individual and 11 historic districts) located within the Attleboro Secondary APE may be affected by the project. Figure 4.8-8 shows the location of historic resources along the Attleboro Secondary. Appendix 4.8-B, presents the potential impacts to historic resources for the Whittenton Diesel Alternative.

Direct Impacts

Direct impacts for the Attleboro Secondary diesel option will be similar to the other project diesel alternatives (discussed above).

The construction of the Attleboro Secondary segment of the Whittenton Diesel Alternative will occur within the right-of-way. Both paralleling stations (listed above) would be constructed within existing right-of-way as well. There are no historic resources located within these construction areas. Therefore, there are no permanent direct impacts of the project on historic resources within the Attleboro Secondary APE.

Indirect Impacts

Indirect impacts for the Attleboro Secondary right-of-way segment of the Whittenton diesel option will be similar to the other project diesel alternatives described above.

The introduction of additional rail service will result in increased noise during operations from train noise and horn blowing at grade crossings. The noise increase will cause moderate to severe, or severe noise at residential, contemplative, and quiet setting historic resources at the following grade crossing locations. These specific areas and resources would likely require sound insulation or barrier mitigation:

- Weir Street and Bow Street grade crossings: High Street Area, Taunton (Map No. Ta.D, Figure 4.8-8)
- Danforth Street grade crossing (Figure 4.8-8):
  - Massachusetts State Hospitals and State Schools, Taunton (Map No. Ta.R)
  - Taunton State Hospital Historic District, Taunton (Map No. Ta.S)
- Tremont Street grade crossing (Figure 4.8-8):
  - Tremont Street Area, Taunton (Map No. Ta.T)
  - Hodges Avenue Area, Taunton (Map No. Ta.U)
- Winthrop Street and Webster Street grade crossings: Harrison Street Area, Taunton (Map No. Ta.V, Ta.D; Figure 4.8-8)
- Porter Street and Cohannet Street grade crossings (Figure 4.8-8):
  - St. Thomas Episcopal Church, Taunton (Map No. Ta.208, Ta.C)

  - o Henry G. Brownell House, Taunton (Elks Lodge No. 150) (Map No. Ta.211, Ta.C)

- Winthrop Street, Porter Street, and Cohannet Street grade crossings (Figure 4.8-8):

  - o Lord-Baylies-Bennett House, Taunton (Taunton Masonic Lodge) (Map No. Ta.245, Ta.C)

  - o Samuel Washburn House, Taunton (Map No. Ta.246, Ta.C)

- Winthrop Street and Cohannet Street grade crossings: Samuel Colby House, Taunton (Map No. Ta.254, Ta.C; Figure 4.8-8)

- Winthrop Street grade crossings: J.C. Bartlett House, Taunton (Map No. Ta.266, Ta.C; Figure 4.8-8)

- Barnum Street and Weir Street grade crossings): William Lawrence House, Taunton (Map No. Ta.309, Ta.C; Figure 4.8-8).

Table 4.8-9 (above) summarizes the adverse effects likely to result from reconstructing the Attleboro Secondary right-of-way segment of the Whittenton Diesel Alternative.

Archaeological Resources

The Attleboro Secondary right-of-way APE of the Whittenton Diesel Alternative includes active freight right-of-way from the Attleboro Bypass and Weir Junction in Taunton. Appendix 4.8-C presents the assessment of potential impacts to archaeological resources within the Attleboro Secondary portion of the APE.

There are no recorded archaeological sites or sensitive areas within the previously disturbed Attleboro Secondary railroad right-of-way. The archaeological survey has not yet been conducted for track improvements that would involve earthmoving outside of the railroad right-of-way within the APE. Project impacts to archaeological resources in these portions of the Attleboro Secondary APE will be assessed when more design information is available, as described in the draft PA (Appendix 4.8-A).

Direct Impacts

Direct impacts for the Attleboro Secondary segment of the Whittenton Diesel Alternative are identical to the electric option.

Indirect Impacts

Indirect impacts for the Attleboro Secondary segment of the Whittenton Diesel Alternative are similar to the electric option with the exception of any impacts from the electrical power infrastructure. Therefore, the diesel option will result in less visual impact. Table 4.8-9 (above) summarizes the adverse effects likely to result from constructing the Whittenton Diesel Alternative.

Archaeological Resources

The Attleboro Secondary right-of-way segment of the Whittenton Electric Alternative is an active line and has not yet been assessed for archaeological resources. Additional cultural resources studies may be needed for this segment of the Whittenton Alternative.

4.8.3.5 Southern Triangle

The Southern Triangle consists of the active freight rail tracks with existing grade crossings of the Fall River Secondary from Myricks Junction in Berkley to Fall River and the New Bedford Main Line from Weir Junction in Taunton to New Bedford and a portion of the Attleboro Secondary between Myricks Junction and Weir Junction. Both diesel and electrification options are being considered for these rail lines.

The Southern Triangle is common to both the Stoughton and Whittenton Alternatives as are the six stations (Battleship Cove, East Taunton, Fall River Depot, Freetown, King's Highway, and Whale's Tooth). Cultural resources survey was conducted for the Southern Triangle elements, and impacts to identified resources are presented below.

Fall River Secondary

Existing freight track would be upgraded and a short segment of the line would be double track south of Myricks Junction, for a distance of 0.61 mile. The remainder of the line would be single track, with the exception of two small double track sections in Freetown and Fall River, 0.62 and 0.71 mile long, respectively.

New catenary supports, wires, and one new traction power facility (TP-11, Paralleling Station [(PS-05]) at a specified location would be constructed along the length of the line for the electrification option. Two new stations would be constructed in Fall River (Battleship Cove and Fall River Depot) and one new station would be constructed in Freetown (Freetown). One new layover facility would be constructed in Fall River, at the Weaver's Cove East location.

Potential Adverse Effects on Historic Resources along the Fall River Secondary Rail Segment

The impacts of the South Coast Rail project to historic resources along the Fall River Secondary line of the Southern Triangle segment of the project may be permanent or temporary, direct or indirect. For the two options (electric and diesel), there is a combined total of 22 historic properties (Table 4.8-10). The locations of these structures and districts along the Fall River Secondary are shown in Figures 4.8-14 through 4.8-16. Appendix 4.8-B, Tables 1 and 2, present the data on the individual structures and districts.

Work elements and impacts discussed in this section apply to, but are not repeated in, subsequent sections for the different electric and diesel alternatives.

Table 4.8-10 Southern Triangle, Fall River Secondary–Affected Historic Resources

Option	Historic – Individual	Historic Districts	Figure	Appendix
Electric	12	10	Figures 4.8-14 through 4.8-16	Appendix 4.8-B
Diesel	6	6	Figures 4.8-14 through 4.8-16	Appendix 4.8-B

Direct Impacts on Historic Resources along the Fall River Secondary Rail Segment

Project work elements for the Fall River Secondary electric option include railroad upgrade (track, railroad bed, bridges and culverts, fencing in populated areas), at-grade crossing improvements (equipment, signage, traffic control), and electrical infrastructure (catenary and traction power

facilities). Direct permanent impacts from work within the existing right-of-way rail corridor are not likely to affect significant historic resources, with the exception of bridges and grade crossings.

Direct impacts from improvements to existing at-grade crossings within historic districts and immediately adjacent to individual historic resources are expected to be minor, provided that no roadway changes are proposed. No direct impacts are anticipated from the new traction power facility, TP-10, Paralleling Station (PS-04), as there are no historic resources on the site. Station impacts are discussed below in Section 4.8.3.6. If noise mitigation insulating treatments on historic buildings are warranted to address indirect effects, these treatments may include new windows and doors. The replacement of windows and doors will have a direct effect on the subject properties and will require design considerations for compatibility with historic resources.

Project work elements and direct impacts for the Fall River Secondary diesel option are identical to the electric option, with the exception of any impacts from the electrical power infrastructure.

Indirect Impacts on Historic Resources along the Fall River Secondary Rail Segment

Indirect impacts from the Fall River Secondary electric option may include auditory, vibration, visual, or other environmental effects on the setting or other character-defining features of individual historic individual properties and districts. Indirect impacts from the addition of upgraded existing track and existing grade crossing rail infrastructure elements in the active right-of-way are generally anticipated to be low.

The introduction of additional rail service will result in increased noise during operations from train noise and horn blowing at grade crossings. The noise increase will cause moderate to severe or severe noise at residential, contemplative, and quiet setting historic resources at the following grade crossing locations. These specific areas and resources could require sound insulation or barrier mitigation to reduce noise impacts. An elastic mat may be placed under the ballast to absorb or reduce vibration levels before they enter the ground and propagate to nearby receptors, as described in Chapter 4.7, *Vibration.*

- At Myricks Street and Mill Street grade crossings: Myricks Street Area, Berkley (Map No. Be.C, Figure 4.8-14)
- At Adams Lane grade crossing: Peirce and Haskins Cemetery, Lakeville (Map No. La.024; Figure 4.8-14)
- At Elm Street, Forge Road, and Richmond Road grade crossings: Slab Bridge Road Area, Freetown (Map No. Ft.C, Figure 4.8-15)
- At Richmond Road and Beechwood Road grade crossings: Richmond Road/ Maple Tree Crossing Bridge, Freetown (Map No. Ft.009, Figure 4.8-14)

Similarly, moderate to severe noise from operations may be experienced at the following resources or districts. These specific areas and resources also would likely require sound insulation or barrier mitigation:

- Assonet Historic District, Freetown (Map No. Ft.D, Figure 4.8-15)

- North Main Street Area, Fall River (Map No. FR.D, Figure 4.8-16)
- Wellington-Brownell Street Area, Fall River (Map No. FR.I, Figure 4.8-16)
- North Burial Ground, Fall River (Map No. FR.K, FR.C; Figure 4.8-16)
- Pearce-Durfee Street Area, Fall River (Map No. FR.M, Figure 4.8-16)
- St. Michael's Roman Catholic Church, Fall River (Map No. FR.050, Figure 4.8-16)
- Al Mac's Diner, Fall River (Map No. FR.070, FR,M; Figure 4.8-16)
- Residence, 524 Durfee Street, Fall River (Map No. FR.081, Figure 4.8-16)

New construction including stations (see Section 4.8.3.6 below), the new traction power facility, catenary systems, bridge modifications and replacements, right-of-way fencing, and noise mitigation barriers may have indirect visual impacts on adjacent historic architectural resources and their settings. The new catenary system along the right-of-way will have a moderate to severe visual effect on several of the residential, commercial, and landscape (but not on industrial or transportation) historic resources throughout the rail corridor (see list in Appendix 4.8-B). The traction power facility TP-11, Paralleling Station (PS-05) will have a moderate to severe visual effect on the Pearce-Durfee Street Area, Fall River (Map No. FR.L, Figure 4.8-16). Right-of-way fencing and noise mitigation barriers in and adjacent to historic districts and individual properties will have an effect on the setting of those historic resources by introducing new chain link fence and solid walls that alter the historic character of the area.

Indirect impacts for the Fall River Secondary diesel option are similar to the electric option, with the exception of those generated by electrical catenary and traction power infrastructure (see list in Appendix 4.8-B). Therefore, the diesel option will result in less visual impact.

Tables 4.8-11 and 4.8-12, below, summarize the adverse effects likely to result from reconstructing the Fall River Secondary, for the electric and diesel alternatives.

Table 4.8-11 Potential Adverse Effects to Historic Resources, Fall River Secondary (Electric Alternatives)

Map ID	Town	Resource	Direct Physical	Indirect Noise	Indirect Visual	Adverse Effects
La.024	Lakeville	Peirce and Haskins Cemetery	No	Yes: Severe train and horn noise	Yes: Moderate, in vicinity of new catenary	Noise Visual

Potential Adverse Effects on Archaeological Resources along the Fall River Secondary Rail Segment

The Fall River Secondary Electric and Diesel APE includes the active freight railroad right-of-way between Myricks Junction in Taunton and Fall River, and any other work areas including electrification infrastructure that would involve earth moving outside of the previously disturbed railroad right-of-way. Appendix 4.8-C presents the assessment of potential impacts to archaeological resources (Table 4.8-13) within the Fall River Secondary portion of the Southern Triangle APE.

Table 4.8-13 Archaeological Sites Identified on the Fall River Secondary Rail Segment

Site Name	Identified Cultural Deposits	Preliminary (Approximate) Site Boundaries	NR eligibility/ recommendation	Project Alternative
Quartz Vein Site	15 chipping debris	Within right-of-way: 23-x-77 m (1771 sq. m)	NR eligible	Stoughton and Whittenton
Circling Hawk Site	46 pre-contact materials: chipping debris, 1 biface, 1 projectile point, fire-cracked rock, calcined bone, shell	Within right-of-way: 25-x-178 m (4450 sq. m)	NR eligible	Stoughton and Whittenton
Cold Toad Site	21 pre-contact materials: chipping debris, 1 biface, fire-cracked rock, hearth or cooking pit feature	Within right-of-way: 10-x-40 m (400 sq m)	NR eligible	Stoughton and Whittenton
Overlook Site North	95 pre-contact materials: chipping debris, aboriginal pottery, cut/butchered mammal bone, oyster shell	Within LOD: 15-x-65 m (975 sq m)	NR eligible	Stoughton and Whittenton
Overlook Site South	74 pre-contact materials: chipping debris, oyster and quahog shell	Within LOD: 15-x-125 m (1875 sq. m)	NR eligible	Stoughton and Whittenton
Landowner's Folly Site	3 chipping debris	Within proposed station footprint: two find spots, each 10-x-10 m (100 sq. m) (total 200 sq. m)	Not NR eligible (disturbed context)	Stoughton and Whittenton
Braley Cemetery (MHC #FRE.823)	Contains over 150 marked burials dating from the early 1800s (pre-railroad) to present-day	Three cemetery lots (two town-owned, one private); each lot measures about 0.5 acre; total 1.49 acres (modern assessor's maps); cemetery frontage right-of-way : 45 m (west); 82 m (east)	Not NR eligible; marked and unmarked burials adjacent to cut railroad embankments	Stoughton and Whittenton

A 1.6-mile-long segment of the Fall River Secondary line lies within the Lower Taunton River Basin Archaeological District in Freetown. This archaeological district contains a number of significant archaeological sites including pre-contact/contact period Native American resources and sensitive lands where undocumented sites may be present. A nineteenth-century mill complex is also adjacent to the rail right-of-way, outside of the archaeological district. The intensive (locational) survey of the Fall River Secondary right-of-way identified five pre-contact archaeological sites, all of which have been determined by the Corps, in consultation with the Massachusetts SHPO and the Aquinnah THPO, to be eligible for the National Register.

For the electric option, there is the possibility that proposed overhead catenary structure support footings could extend into archaeologically sensitive strata below rail bed disturbance and fill deposits. Specific sensitivity areas would be determined based on a review of soil borings and/or a detailed soil profile of the right-of-way using soil boring logs. The location, number and size of soil borings would be determined to minimize impacts to archeological resources as a result of field testing. An intensive (locational) survey may be needed in sensitive areas where direct physical construction impacts are planned. Archaeological surveys for track improvements including electrification infrastructure that would involve earthmoving below or outside of the previously disturbed railroad right-of-way within the APE will be completed as more detailed design information becomes available. Project impacts to archaeological resources in these portions of the Fall River Secondary Electric and Diesel APE will be assessed prior to completion of environmental review and when more detailed design information is available, as described in the draft PA (Appendix 4.8-A).

New Bedford Main Line

Existing freight track would be upgraded and the line would be double track for the entire length between Weir Junction and downtown New Bedford (which includes a portion of the Attleboro Secondary between Weir Junction and Myricks Junction), a distance of 18.51 miles. Passing sidings may also be an option instead of the double track. The section between Weir Junction and Cotley Junction would be a triple track section to allow for freight movement around a proposed station (Taunton Depot).

New catenary supports, wires, and up to three traction power facilities at specified locations would be constructed along the length of the line for the electrification option. The traction power facilities are:

- TP-07, Substation (TPSS-2) as part of the Stoughton and Whittenton Electric Alternative
- TP-09, Paralleling Station (PS-6) as part of Stoughton and Whittenton Electric Alternative

Two new train stations would be constructed in New Bedford (King's Highway and Whale's Tooth) and one new station (Taunton Depot) would be constructed in Taunton. One new layover facility would be constructed in New Bedford, at the Wamsutta location.

Potential Adverse Effects on Historic Resources along the New Bedford Main Line

The impacts of the South Coast Rail project to historic resources along the New Bedford Main Line of the Southern Triangle segment of the project may be permanent or temporary, direct or indirect. For the two options (electric and diesel), there is a combined total of 8 historic properties (Tables 4.8-14 through 4.8-16). The locations of these structures and districts along the Attleboro Secondary and New

Bedford Main Line are shown in Figures 4.8-9 through 4.8-13. Appendix 4.8-B presents the data on the individual structures and districts.

Table 4.8-14 Southern Triangle, New Bedford Main Line Affected Historic Resources

Option	Historic – Individual	Historic Districts	Figure	Appendix
Electric	4	4	Figures 4.8-9 through 4.8-13	Appendix 4.8-B
Diesel	4	4	Figures 4.8-9 through 4.8-13	Appendix 4.8-B

Direct Impacts on Historic Resources along the New Bedford Main Line Rail Segment

Project work elements and direct impacts for the New Bedford Main Line electric option will be similar to the other electric alternatives.

No National Register-listed, or determined eligible historic properties are located in the direct impact APEs for the three traction power sites proposed for the Stoughton Electric Alternative. Therefore, there will be no direct effects to historic properties at these locations.

Project work elements and direct impacts for the New Bedford Main Line diesel option are identical to the electric option, as there are no direct impacts from the electrical power infrastructure.

Indirect Impacts on Historic Resources along the New Bedford Main Line Rail Segment

Indirect impacts from the New Bedford Main Line electric option will be similar to the other electric alternatives.

The introduction of additional rail service will result in increased noise during operations from train noise and horn blowing at grade crossings. The noise increase will cause moderate to severe, or severe noise at residential, contemplative, and quiet setting historic resources at the following grade crossing locations. These specific areas and resources would likely require sound insulation or barrier mitigation:

- Padelford Street grade crossing: 1 Macomber Street, Berkley (Map No. Be.006. Figure 4.8-10)
- Malbone Street grade crossing: Malbone Street, Lakeville (Map No. La.C, Figure 4.8-11)

Similarly, moderate to severe noise from operations may be experienced for historic properties within the Acushnet Heights Historic District, New Bedford (Map No. NB.C, Figure 4.8-13). Sound insulation or barrier mitigation would likely be needed at some of the properties within the district.

New construction including stations (see Section 4.8.3.6 below), traction power facilities, catenary systems, bridge modifications and replacements, right-of-way fencing, and noise mitigation barriers changes may have indirect visual impacts on adjacent historic architectural resources and their settings. The new catenary system along the right-of-way will have a moderate to severe visual effects on all the residential, commercial, and landscape (but not on industrial or transportation) historic resources throughout the rail corridor (see list in Appendix 4.8-B, Table 1).

One traction power facility may have a visual effect on historic properties through the introduction of modern power structures that could alter the historic setting:

- TP-09, Paralleling Station (PS-6) as part of Stoughton and Whittenton Electric Alternatives on four historic properties or districts in New Bedford (Figure 4.8-13):
  - Acushnet Heights Historic District (Map No. NB.C)
  - Dawson Building (Map No. NB.065)
  - Wamsutta Mills Historic District (Map No. NB.D)

Indirect impacts for the New Bedford Main Line diesel option are similar to the electric option, with the exception of those generated by electrical catenary and traction power infrastructure (see list in Appendix 4.8-B). Therefore, the diesel option would result in less visual impact.

Table 4.8-15 and Table 4.8-16, below, summarize the adverse effects likely to result from reconstructing the New Bedford Main Line, for the electric and diesel alternatives.

Table 4.8-15 Potential Adverse Effects to Historic Resources, New Bedford Main Line (Electric Alternatives)

Map ID	Town	Resource	Direct Physical	Indirect Noise	Indirect Visual	Adverse Effects
La.C	Lakeville	Assonet Cedar Swamp Area	No	Yes: Moderate to severe train and horn noise	Yes: Moderate to severe, portions of area are in vicinity of new catenary	Noise Visual
Be.C	Berkley	Myricks Street Area	No	Yes: Moderate to severe train and horn noise	Yes: Moderate to severe, portions of area are in vicinity of new catenary, and traction power facility	Noise Visual
Be.006	Berkley	Residence, 1 Macomber St	No	Yes: Severe train and horn noise	Yes: Severe, adjacent to new catenary	Noise Visual
NB.C	New Bedford	Acushnet Heights Historic District	No	Yes: Moderate to severe train noise	Yes: Moderate, in vicinity of new catenary and layover facility	Noise Visual
NB.D	New Bedford	Wamsutta Mills Historic District	No	Yes: Moderate to severe train noise	Yes: Moderate, in vicinity of new catenary and layover facility	Noise (to residential area) Visual
NB.029	New Bedford	Christ Presbyterian Church	No	No	Yes: Moderate, in vicinity of new catenary	Visual
NB.053	New Bedford	Purchase Street Fire Station	No	Yes: Moderate train noise	Yes: Moderate, in vicinity of new catenary	Visual
NB.065	New Bedford	Dawson Building	No	No	Yes: Moderate, in vicinity of new catenary and traction power facility	Visual

Table 4.8-16 Potential Adverse Effects to Historic Resources, New Bedford Main Line (Diesel Alternatives)

Potential Adverse Effects on Archaeological Resources along the New Bedford Main Line

The New Bedford Main Line Electric and Diesel APE includes the active freight railroad right-of-way between Weir Junction in Taunton and New Bedford, and any other work areas including electrification infrastructure that would involve earthmoving outside of the previously disturbed railroad right-of-way. Appendix 4.8-C presents the assessment of potential impacts to archaeological resources within the New Bedford Main Line portion of the Southern Triangle APE.

Two historic cemeteries are located adjacent to the New Bedford Main Line right-of-way. The cemeteries are:

- Howland Cemetery, MHC #LAK.806 in Lakeville
- Braley Cemetery, MHC #FRE.823 in Freetown

Historic research has concluded that graves are unlikely to be located within the right-of-way, but marked and unmarked interments may be immediately adjacent to the right-of-way.

For the electric option, there is the possibility that proposed overhead catenary structure support footings could extend into archaeologically sensitive strata below rail bed disturbance and fill deposits within the New Bedford Main Line right-of-way. Specific sensitivity areas would be determined based on a review of soil borings and/or a detailed soil profile of the right-of-way using soil boring logs. An intensive (locational) survey may be needed in sensitive areas where direct physical construction

impacts are planned. Project impacts to archaeological resources will be assessed prior to completion of environmental review and when more detailed design information is available, as described in the draft PA (Appendix 4.8-A).

The archaeological survey for track improvements including electrification infrastructure that would involve earthmoving below or outside of the previously disturbed railroad right-of-way within the APE will be conducted during subsequent stages of environmental review. Impacts to archaeological resources in these portions of the New Bedford Main Line Electric and Diesel APE will be assessed prior to completion of environmental review and when more detailed design information is available, as described in the draft PA (Appendix 4.8-A).

4.8.3.6 Stations

There are 12 stations proposed for new construction or improvements for the Stoughton and Whittenton Alternatives, including the Southern Triangle (electric and diesel). Station plans are conceptual at this point, consisting of general layouts and footprints within specified larger parcels. Rail stations will typically consist of a raised 800-foot long platform, canopy, parking lot, signage and lighting.

Conceptual plans were used for the data collection and analysis of cultural resources at the proposed stations. The potential impacts to identified cultural resources station concepts are presented below. The discussions below detail the results of investigations to date at the various stations. Appendix 4.8-C, Table 5 presents the assessment of potential impacts to archaeological resources within the Station APEs. Appendix 4.8-C, Table 6 presents the assessment of potential impacts to archaeological resources with the layover facility APEs. The impacts to the historic structures, areas, and districts are summarized on Appendix 4.8-B, Table 11 and discussed in text below.

Battleship Cove

The Battleship Cove Station would be a new station constructed behind the Ponte Delgada monument along Water Street on an approximately 2.2-acre parcel near the southern terminus of the Fall River Secondary. It would serve all of the rail alternatives. The station would be designed to serve walk-in customers and pick up-drop off customers with no parking. The City of Fall River constructed a pickup-drop off loop road for the future commuter rail station as part of the Ponte Delgada monument construction.

Historic Resources

The proposed Battleship Cove Station at the terminus of the Fall River Secondary is adjacent to the American Printing Company–Metacomet Mill (Map Nos. FR.N, FR.C), the American Printing Company Machine Shop (Map No. FR.088), and the Borden and Remington Company (Map No. FR.089) as shown in Figure 4.8-16. There are no historic resources on the site; therefore, there will be no direct impacts to historic resources.

The introduction of a new station may have indirect visual effects on these three historic properties through the introduction of modern station structures that alter the historic setting. Noise, vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

Archaeological Resources

There are no recorded archaeological sites or identified archaeologically sensitive areas within the 2.2-acre project parcel. No project impacts to archaeological resources are anticipated by the construction of this proposed station for the rail alternatives.

Canton Center

Canton Center Station is an existing station site off of Washington Street that would be modified to accommodate a second track. Two new 800-foot-long low-level platforms with mini-high platforms would be constructed (one adjacent to each track). Modifications to the tracks and platforms would require minor changes to the parking layout in the existing lots near the station, and no adjustments to the amount of existing parking spaces would be expected.

Historic Resources

Canton Center Station is not a historic resource but is adjacent to the Canton Center Area (Map No. Ca.C) as shown in Figure 4.8-2. There are no historic resources on the site; therefore, there will be no direct impacts to historic resources.

Improvements to the existing station may have indirect visual effects on Canton Center Area through the introduction of modern station structures that alter the historic setting. Noise, vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

Archaeological Resources

No archaeological survey has been conducted; however, the current conceptual plan indicates that the station modification work will be contained within the existing disturbed railroad right-of-way and paved station site. Therefore, no project impacts to archaeological resources are anticipated.

Dana Street Station in Downtown Taunton

The Dana Street Station would be located just south of the Danforth Street grade crossing, within walking distance of downtown Taunton. It would only serve the Whittenton Alternatives.

Historic Resources

The Taunton State Hospital property (Map No. Ta.S), which is listed in the National Register, is located on the opposite side of Dana Street to the east. The new station may have an indirect effect on the historic architectural and setting qualities of the Taunton State Hospital; however, these are not anticipated to be substantially different from existing conditions so the effect would not be adverse. Noise, vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

The Staples Coal Company (Map No. Ta.160) is located at 28 Dana Street south of the station APE. The introduction of a new station could have indirect visual effects on this historic property through the introduction of modern station structures and parking that alter the historic setting. However, the effect will not be adverse because of the existing dense urban character of the surrounding area and the original industrial/transportation related function of the historic building. Noise, vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

Archaeological Resources

The proposed Dana Street Station was assigned moderate sensitivity for primarily pre-contact Native American archaeological resources. A review of the 2006 soil test pit data indicates that the fill is shallow in some portions of the proposed station footprint parcel, perhaps as little as 6 inches, but does extend up to 5 feet deep in other portions of the proposed station footprint. Soil borings planned for the proposed station footprint as design advances may provide information that could be used to refine the sensitivity assessment and determine the presence and depth of sensitive strata. Sensitive areas would likely require a combination of hand and machine-assisted subsurface testing as part of an intensive (locational) archaeological survey. The intensive survey is recommended for any sensitive portions of the proposed Dana Street Station footprint that cannot be avoided during project design advances. The survey would be designed to locate any potentially significant archaeological resources that may be impacted by the project.

Easton Village

The Easton Village Station would be a new station consisting of platform, canopy, and drop-off parking lot only constructed on an approximately 1-acre parcel adjacent to Sullivan Avenue in North Easton Village along the Stoughton Line (Figure 4.8-4). It would serve the rail alternatives.

Historic Resources

The proposed Easton Village Station on the Stoughton Line in Easton (Figure 4.8-4) is located immediately adjacent to the Easton Old Colony Railroad Station (Map No. Ea.003), which is part of the H.H. Richardson Historic District NHL (Map No. Ea.D) and is within the National Register listed North Easton Historic District (Map No. Ea.B).

The proposed station site abuts important contributing properties of this district that are associated with the Ames Shovel Works. The introduction of a new station will have a direct effect on the Stoughton Line through construction of new platform and related features on the railroad embankment. The new station will have indirect visual effects on the surrounding National Register and NHL properties through the introduction of modern station structures and parking that alter the historic setting. Noise, vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

Archaeological Resources

The northern portion of the 1-acre project parcel is assessed as having moderate sensitivity for 1) pre-contact Native American habitation and resource procurement/processing sites; and 2) undocumented eighteenth and nineteenth-century industrial and railroad-related resources beneath the built-up railroad embankment.

An intensive (locational) archaeological survey was conducted and located one post-contact archaeological site. The site is not eligible for the National Register due to poor physical integrity and low research potential.

Fall River Depot

The Fall River Depot would be a new train station constructed on an approximately 8-acre parcel, 1 mile north of downtown Fall River at Route 79 and Davol Street along the Fall River Secondary (Figure 4.8-16). It would serve all of the rail alternatives.

Historic Resources

There are no historic resources on the site of the proposed Fall River Depot Station on the Fall River Secondary. Therefore, there will be no direct impacts to historic resources

The proposed Station is located across the rail right-of-way from the Pearce-Durfee Street Area (Map No. FR.L). This historic property has been determined eligible for inclusion in the National Register. The introduction of a new station will have indirect visual effects on this historic property through the introduction of modern station structures and parking that could alter the historic setting. However, the effect would not be adverse due to the industrial character of the adjacent part of the Pearce-Durfee Street Area and the presence of the highway. Noise, vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

Archaeological Resources

There are no recorded archaeological sites or identified archaeologically sensitive areas within the 8-acre project parcel. No project impacts to archaeological resources are anticipated by the construction of this proposed station.

Freetown

The Freetown Station would be a new train station constructed on an 18-acre parcel situated on South Main Street and west of the Fall River Secondary right-of-way (Figure 4.8-15). The parcel currently contains a self-storage business, and is near the Fall River Executive Park and the proposed Riverfront Park. It would serve all of the rail alternatives.

Historic Resources

The Freetown Station does not have any historic resources on the proposed site or within the APE. Therefore, there would be no impacts to historic resources.

Archaeological Resources

The proposed Freetown Station lies within the Lower Taunton River Basin Archaeological District. The 18-acre project parcel contains areas of moderate and high archaeological sensitivity for pre-contact Native American habitation and resource procurement/processing sites. However, the site has been largely disturbed by land clearing and scraping/stockpiling of soils which compromised its integrity well in advance of this commuter rail proposal.

An intensive (locational) archaeological survey was conducted and located one pre-contact archaeological site, the Landowner's Folly Site. The site is not eligible for the National Register due to poor physical integrity and low research potential.

King's Highway

The King's Highway Station would be a new train station constructed on a 55-acre parcel within a dense commercial strip off of King's Highway in New Bedford east of Route 140 along the New Bedford Main Line (Figure 4.8-13). The new station would occupy part of a site that is an existing shopping plaza. It would serve all of the rail alternatives.

Historic Resources

The King's Highway Station does not have any historic resources on the proposed site or within the APE. There will be no impacts to historic resources.

Archaeological Resources

The 55-acre project parcel contains areas of moderate archaeological sensitivity for pre-contact Native American habitation and resource procurement/processing sites. In addition, buildings are documented as present between 1895 and 1911. Though these buildings have been razed, undocumented archaeological deposits related to this period of site use may be present in the north part of the parcel.

The current conceptual plan indicates that the proposed work will be contained within the existing disturbed railroad right-of-way and paved shopping plaza in areas assigned low archaeological sensitivity. No project impacts to archaeological resources are anticipated in these previously disturbed areas.

North Easton

The North Easton Station (Figure 4.8-3) would be a new train station constructed on an approximately 10-acre parcel. The parcel lies behind an existing retail plaza anchored by Roche Brothers shopping plaza along the Stoughton line. New medical buildings have been recently constructed and two additional buildings are planned. The station would serve the rail alternatives.

Historic Resources

North Easton Station does not have any historic properties on the proposed site or within the APE. There would be no impacts to historic resources.

Archaeological Resources

The 10-acre project parcel contained an area of moderate archaeological sensitivity for pre-contact Native American habitation and resource procurement/processing sites as well as under-documented post-contact EuroAmerican sites.

An intensive (locational) archaeological survey was conducted and located one post-contact sheet refuse deposit. This deposit is not eligible for the National Register due to fair physical integrity and low research potential.

Raynham Park

The Raynham Park Station would be located at the former Raynham-Taunton Greyhound Park off of Route 138 (Figure 4.8-5). The new station would be constructed on a less than 5-acre parcel along the Stoughton line. The station would serve the Stoughton Alternatives including the Whittenton variations.

Historic Resources

No historic properties are located on the Raynham Park Station parcel nor do any exist within the station APE. There will be no impacts to historic resources.

Archaeological Resources

There are no recorded archaeological sites or identified archaeologically sensitive areas within the Raynham Park Station parcel. The station is within the rail APE and has been subjected to prior disturbance. No project impacts to archaeological resources are anticipated by the construction of this proposed station.

Stoughton (Existing Station)

The Stoughton Station is an existing commuter rail station located off of Route 138 near Stoughton Center along the Stoughton line (Figure 4.8-3). The existing Stoughton Station would be relocated to accommodate a second track and the existing station would be decommissioned. Modifications to the station property may need to be made necessary to ensure safety.

Historic Resources

The existing station (Stoughton Station; Map No. St.025) is an individual historic property and is within the Downtown Stoughton Area (Map No. St.B). The Mystic Rubber Company (Map No. St.024) is within the station APE.

The Meade Rubber Company (Map No. St.046) will be demolished under the current plan. Modifications necessary to accommodate a second track and decommissioning of the station may have an indirect effect on the historic architectural qualities of the station, the Area, and the Mystic Rubber Company.

Archaeological Resources

No archaeological survey has been completed at the station. The current conceptual plan indicates that the proposed work will be contained within the existing disturbed railroad right-of-way and paved station site. If the work is confined to existing built elements, no archaeological survey is warranted. No project impacts to archaeological resources are anticipated under the proposed conceptual plan.

Stoughton (New Station)

A new station would be constructed in Stoughton south of the existing station location between Porter and Wyman streets to a new location south of the Wyman Street at-grade crossing. Two new 800-foot long, full-length high-level platforms would be constructed (one adjacent to each track) at the new station site. A pedestrian bridge with stairs and ramps would connect the two platforms. These modifications to the tracks and platforms would require a new parking layout to the west of the platforms. This station would continue to serve walk-in, bike-in and drive-in customers. It would serve all of the rail alternatives.

Historic Resources

The proposed relocated Stoughton Station is not within any National Register Historic District or Area, and is south of the Downtown Stoughton Area (eligible for listing). The site contains one property which is eligible for listing in the National Register: the Meade Rubber Company Building (Map No. St 046) at 25 Brock Street. The Meade Rubber Company Building is eligible for National Register listing for its associations with the locally significant rubber industry as an intact example of an early 20th century industrial loft. The proposed relocated station would require that this building be demolished, resulting in an adverse effect.

Archaeological Resources

The proposed relocated Stoughton Station project area including the realigned tracks was assigned moderate sensitivity for pre-contact Native American and nineteenth-early twentieth century post-contact period archaeological resources. The potential post-contact period archaeological resources are associated in part with the Meade Rubber Company property, eligible for listing in the National Register, and which would be demolished to accommodate the relocated station footprint. Soil borings planned for the proposed station footprint and track realignment as design advances may provide information that could be used to refine the sensitivity assessment and determine the presence and depth of sensitive strata. Sensitive areas would likely require a combination of hand and machine-assisted subsurface testing as part of an intensive (locational) archaeological survey. The intensive survey is recommended for any sensitive portions of the proposed relocated Stoughton Station footprint and realigned tracks that cannot be avoided during project design advances. The survey would be designed to locate any potentially significant pre-contact and post-contact archaeological resources that may be impacted by the project.

Taunton (Dean Street)

The Taunton Station (Dean Street) would be a new train station constructed on an 8-acre parcel. The parcel is located off of Railroad Avenue near the intersection of Route 44 (Dean Street) and Arlington Street in Taunton along the Stoughton line (Figure 4.8-6). The station would only serve the Stoughton Alternatives.

Historic Resources

There are no historic properties on the Taunton Station parcel. Therefore, there will be no direct impacts to historic resources.

The station parcel is adjacent to the Taunton Center Area (Ta.B) and the Old Colony Railroad Station (Map No. Ta.019). Introduction of a new station may have indirect visual effects on these two historic properties through the introduction of modern station structures and parking that alter the historic setting. Noise, vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

Archaeological Resources

There are no recorded archaeological sites or identified archaeologically sensitive areas within the 8-acre project parcel. No project impacts to archaeological resources are anticipated by the construction of this proposed station.

Taunton Depot

The new Taunton Depot (formerly called East Taunton (North) Station) train station would be constructed on an approximately 14-acre parcel. The parcel is located off of Route 140 at the rear of an existing Target and Home Depot shopping plaza on the New Bedford Main Line (Figure 4.8-9). The station would serve all the rail alternatives.

Historic Resources

No historic properties are located on the proposed site of the Taunton Depot Station. Therefore, there will be no direct effects to historic properties.

The historic Hart Street Area (Map No. Ta.L) is in the station APE as shown in Figure 4.8-8. The introduction of a new station would not affect the visual environment. Noise, vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

Archaeological Resources

The current conceptual plan indicates that the proposed work will be contained within the existing disturbed (southern) portion of the parcel behind the shopping plaza. This part of the parcel is assigned low archaeological sensitivity. No project impacts to archaeological resources are anticipated.

There is one recorded pre-contact archaeological site (19-BR-592) within the northern part of the 14-acre project parcel. The approximate 5-acre area containing the recorded archaeological site is assessed as having high sensitivity for potentially significant cultural deposits. The current conceptual plan indicates that no work in or use of this part of the parcel is proposed and therefore, no project impacts to archaeological resources would be anticipated.

Whale's Tooth

The Whale's Tooth Station would be a new train station. The station will be constructed on an 8.7-acre parcel off of Acushnet Avenue, east of Route 18 along the New Bedford Main Line (Figure 4.8-13) and service all of the rail alternatives.

The parcel is a paved parking lot constructed by the City of New Bedford in anticipation of the commuter rail project. The parking lot caps a closed superfund site.

Historic Resources

The parcel that will be used for the Whale's Tooth Station does not have any historic properties on it. There will be no direct impacts to historic resources.

The proposed Whale's Tooth Station on the New Bedford Main Line is across John F. Kennedy Highway (Route 18) from the New Bedford Textile School (Map No. NB.069). The introduction of a new station may have indirect visual effects on the New Bedford Textile School; however, due to the intervening highway, the effect will not be adverse. Noise, vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

Archaeological Resources

The entire 8.7-acre project parcel lies within the Acushnet Avenue Waterfront Industrial historic area. This location is assessed as having a high archaeological sensitivity for pre-contact Native American habitation and resource procurement/processing sites, and documented nineteenth-century industrial and commercial sites. The archaeologically sensitive strata, if present, would be located below the raised and capped paved parking lot and the capped Superfund site soils. The current conceptual plan indicates that the proposed work will be contained within the existing disturbed railroad right-of-way and the existing Whale's Tooth paved parking lot. No project impacts to archaeological resources are anticipated.

4.8.3.7 Layover Facilities

Two train layover facilities are planned for the Southern Triangle; one each at or near the end of the Fall River Secondary (Weaver's Cove) and the New Bedford Main (Wamsutta East) Lines. Train layover facility plans are conceptual at this point, consisting only of general layouts and footprints within specified larger parcels. Current, refined conceptual plans for these facilities may be slightly different, and were also reviewed for potential impacts to archaeological resources.

Wamsutta

The Wamsutta site overnight layover facility would be constructed on an approximately 8-acre parcel between Route 18 and Herman Melville Boulevard along the New Bedford Main Line (Figure 4.8-13). It is located on the east side of the right-of-way, opposite the proposed Whale's Tooth Station and adjacent to an existing CSX freight yard. The layover facility would serve all of the rail alternatives.

Historic Resources

The Wamsutta Street Layover Facility does not have any historic properties on the proposed site; therefore, there will be no direct impacts to historic resources.

The Wamsutta Layover Facility is located on the east side of the New Bedford Main Line rail between Wamsutta Street and the proposed Whale's Tooth Station. The Wamsutta Mill Historic District (Map No. NB.D) and the Revere Copper Products mill (Map No. NB.080) are both located within the APE as shown in Figure 4.8-13. The introduction of a layover facility could have indirect visual and noise effects on the two nearby historic properties. Because the site is adjacent to the existing freight yard and will constitute an expansion of similar rail use, the visual impacts to the historic setting is likely to not be adverse. There will be no noise impacts to the adjacent historic industrial buildings, which are not a category of noise sensitive receptors under the FTA criteria. Vibration, traffic, atmospheric, and cumulative effects are anticipated to be minimal.

Archaeological Resources

The entire 8-acre project parcel is assessed as having a high archaeological sensitivity for pre-contact Native American habitation, resource procurement/processing sites, and documented post-contact Euro-American domestic, commercial/wharves, and railroad-related structures. This also includes cultural deposits within the Acushnet Avenue Waterfront Industrial historic area. The archaeologically sensitive strata are located below the capped Superfund site soils.

The current conceptual plan indicates that the proposed work will be contained within the existing disturbed railroad right-of-way/rail yard and capped Superfund site soils. Therefore, no project impacts to archaeological resources are anticipated.

Weaver's Cove East

The Weaver's Cove East site layover facility would be constructed on the east side of the railroad right-of-way, opposite the proposed Weaver's Cove LNG Site, approximately 2.5 miles from the southern terminus of the Fall River Secondary (Figure 4.8-16). The layover facility would serve all of the rail alternatives. A parcel on the west side of the railroad right-of-way within the proposed Weaver's Cove LNG Site is also being considered.

Historic Resources

The historic survey completed for the Weaver's Cove layover facility parcel on the west side of the railroad right-of-way encompasses the historic resources in the APE of the current site on the east side of the right-of-way (see Figure 4.8-16). Based on the survey completed for the west site, the Weaver's Cove East site overlaps into a portion of the North Main Street Area (Map No. FR.D) that is eligible for the National Register. This part of the area has no buildings. The construction of the layover facility would be an adverse effect as it would change the visual setting and the character of the area.

Two historic properties are located in the layover facility APE: the National Register-listed Squire William B. Canedy House (Map No. FR.012) and the National Register-eligible William J. Wiley Middle School (Map No. FR.013).

The William B. Canedy House would be separated from the layover facility by a modern building and outbuildings, and then by the tracks. There would be no adverse visual impact because the layover facility would not substantially alter the historic setting of the house, which is already converted to industrial uses (i.e. the tank farm). There would be no noise impacts that would require modifications to the building and no land acquisition from the property.

The William J. Wiley Middle School is located on the opposite (east) side of Main Street from the facility and separated from it by this major roadway and several modern buildings. There would be no property acquisition, no change in the setting of the school, and no noise impacts that would require modifications to the exterior of the building.

There will be no adverse effect to the nearby National Register-listed Squire William B. Canedy House and the National Register-eligible William J. Wiley Middle School.

Archaeological Resources

The project parcel on the west side of the railroad right-of-way within the proposed Weaver's Cove LNG Site was previously subjected to an archaeological reconnaissance survey in 2003. No areas of archaeological sensitivity were identified in the previously disturbed parcel, and no further work was deemed necessary.

The project parcel on the east side of the railroad right-of-way opposite the Weaver's Cove LNG Site has not been subjected to archaeological reconnaissance survey. An archaeological reconnaissance survey is needed to assess the archaeological sensitivity of this parcel. An intensive (locational) survey may be needed to identify archaeological sites in sensitive areas. Project impacts to archaeological resources for the Weaver's Cove East parcel will be assessed when more design information is available, as described in the PA (Appendix 4.8-A).

4.8.4 Summary of Impacts by Alternative

The following summarizes the potential impacts (direct, indirect, permanent, and temporary) to cultural resources resulting from implementing each of the South Coast Rail alternatives.

The individual components of each element are grouped by alternative, and the expected impacts to historic and archaeological resources are summarized based on a quantitative assessment of the impact on cultural resources that would result from the construction of each component.

4.8.4.1 Stoughton Electric Alternative

The Stoughton Electric Alternative would be comprised of the elements listed in Table 4.8-17, which also includes summaries of the identified known/expected resource types and potential impact(s) from implementing this alternative.

The Stoughton Electric Alternative would result in direct impacts (adverse effects) to five historic properties. In addition, this alternative would have indirect effects to an additional 60 properties as a result of changes in setting and/or increased noise that could affect the setting directly or require noise mitigation that could affect the appearance or setting of a building. It could affect ten archaeological sites for reconstruction of the Stoughton Line and Fall River Secondary. These ten archaeological sites are eligible for the National Register.

Table 4.8-17 Stoughton Electric Alternative–Summary of Impacts

	Historic Resources				National Register–Eligible Archaeological Sites

4.8.4.2 Stoughton Diesel Alternative

The Stoughton Diesel Alternative would be comprised of the same elements as the Stoughton Electric Alternative as listed above but would not include electrical infrastructure. Specifically, the metal structures and wires associated with the overhead catenary system, and the traction power facilities would not be constructed as part of this alternative (except along the Northeast Corridor, as previously

explained). Table 4.8-18 summarizes the impacts to cultural resources potentially resulting from implementing the Stoughton Diesel Alternative.

The Stoughton Diesel Alternative would result in direct impacts (adverse effects) to six historic properties, primarily historic bridges that would require reconstruction or widening, and potential direct impacts at some existing stations that would need to be reconstructed. In addition, this alternative would have indirect effects to an additional 44 properties as a result of changes in setting and/or increased noise that could affect the setting directly or require noise mitigation that could affect the appearance or setting of a building. It could affect ten archaeological sites for reconstruction of the Stoughton Line and Fall River Secondary. These ten archaeological sites are eligible for the National Register.

Table 4.8-18 Stoughton Diesel Alternative–Summary of Impacts

4.8.4.3 Whittenton Electric Alternative

The Whittenton Electric Alternative, as a variation of the Stoughton Electric Alternative, would be comprised of the elements listed in Table 4.8-19, which also include summaries of the identified known/expected resource types and potential impact(s) from implementing this alternative. The Whittenton Electric Alternative would result in direct impacts (adverse effects) to five historic properties. In addition, this alternative would have indirect effects to an additional 65 properties as a

result of changes in setting and/or increased noise that could affect the setting directly or require noise mitigation that could affect the appearance or setting of a building. It could affect eleven archaeological sites that have been determined eligible for the National Register.

Totals	5	32	0	33	11

4.8.4.4 Whittenton Diesel Alternative

The Whittenton Diesel Alternative would be comprised of the same elements as the Whittenton Electric Alternative as listed above but would not include electrical infrastructure. Specifically, the metal structures and wires associated with the overhead catenary system, and the traction power facilities would not be constructed as part of this alternative (except along the Northeast Corridor, as previously explained). Table 4.8-20 summarizes the impacts to cultural resources potentially resulting from implementing the Whittenton Diesel Alternative.

The Whittenton Diesel Alternative would result in direct impacts (adverse effects) to five historic properties. In addition, this alternative would have indirect effects to an additional 44 properties as a result of changes in setting and/or increased noise that could affect the setting directly or require noise

mitigation that could affect the appearance or setting of a building. It could affect two known archaeological sites for reconstruction of the Fall River Secondary. It could affect eleven archaeological sites that have been determined eligible for the National Register.

Table 4.8-20 Whittenton Diesel Alternative–Summary of Impacts

	Historic Resources				National – Register Eligible Archaeological Sites
		Indirect			
Element	Direct	Visual (only)	Noise (only)	Noise + Visual

4.8.4.5 Summary of Impacts

The overall impacts to historic and archaeological resources resulting from improving or constructing the rail alternatives vary considerably between the alternative alignments (Table 4.8-21). Each of the alternatives would be similar in their adverse effects to historic structures. The majority of these direct effects, for all alternatives, would result from reconstructing historic bridges to accommodate an additional track, or to meet Federal Railroad Administration loading standards for commuter rail trains. Each of the alternatives would also result in indirect impacts to historic properties as a result in the change in setting (visual impacts) or increased noise (which could affect quiet setting or could result in noise mitigation that would alter the appearance or setting of a structure). These indirect effects (only visual, only noise, or a combination of the two) would impact the largest number of properties (72) for the Whittenton Electric Alternative.

Each of the alternatives would also have the potential to affect as yet to be determined archaeological resources and areas of archaeological sensitivity (which would require further investigation to determine if archaeological resources were present). There may also be the potential that traditional cultural properties may be affected. Should such potential exist, this would be resolved through dialogue with the federally-recognized Indian Tribes known to have an interest in impacts to traditional cultural properties located within upon their historical aboriginal lands.

Table 4.8-21 Summary of Potential Impacts to Historic and Archaeological Resources

Alternative	Historic Resources Direct	Indirect Visual	Indirect Noise	Indirect Noise + Visual	National Register-Eligible Archaeological Sites
Stoughton Electric	5	25	0	27	10*
Stoughton Diesel	5	9	19	19	10
Whittenton Electric	5	32	0	33	11*
Whittenton Diesel	5	11	14	19	11

*Impacts are contingent upon the results of additional cultural resource investigations that may be necessary for electrification infrastructure.

4.8.5 Mitigation

This section summarizes the mitigation measures that may be considered to avoid, minimize, or mitigate the potential impacts on historic and archaeological resources resulting from the implementation of the South Coast Rail project alternatives. The specific mitigation will be informed by additional design detail.

Cultural resources are defined as archaeological sites; historic buildings, structures, objects, and districts; and traditional cultural properties including both individual sites and landscapes. Consultation has been initiated with federally recognized Indian Tribes; however, no written information has been received to date and traditional cultural properties are not considered in the discussions below. The discussion below considers the regulatory requirements of the National Environmental Policy Act (NEPA), §106 of the National Historic Preservation Act (NHPA), and regulatory guidance detailed in National Register Bulletin 45, *Guidelines for Evaluating and Registering Archaeological Properties* (Little et al. 2000).

Assessment of impact to cultural resources was based on the Corps' methodology as described in Appendix C - Procedures for the Protection of Historic Properties[4] of 33 CFR Part 325 - Processing of Department of the Army Permits (Appendix C). Appendix C identifies the procedures to be followed by the Corps to fulfill the requirements set forth in the National Historic Preservation Act (NHPA), other applicable historic preservation laws, and Presidential directives as they relate to the regulatory program of the Corps of Engineers (33 CFR Parts 320-334).

The central concept in the Corps methodology is the "Permit Area," as defined in Appendix C. The term "permit area" as used in Appendix C means those areas comprising the waters of the United States that will be directly affected by the proposed work or structures and uplands directly affected as a result of

[4] AUTHORITY: 33 U.S.C. 401 et seq., 33 U.S.C. 1344, 33 U.S.C. 1413.

authorizing the work or structures. The following three tests must all be satisfied for an activity undertaken outside the waters of the United States to be included within the "permit area":

- Such activity would not occur but for the authorization of the work or structures within the waters of the United States;
- Such activity must be integrally related to the work or structures to be authorized within waters of the United States. Or, conversely, the work or structures to be authorized must be essential to the completeness of the overall project or program; and,
- Such activity must be directly associated (first order impact) with the work or structures to be authorized.

The District Engineer takes into account the effects, if any, of proposed undertakings on historic properties both within and beyond the waters of the U.S. pursuant to Section 110(f) of the NHPA. The District Engineer, where the undertaking that is the subject of a permit action may directly and adversely affect any National Historic Landmark, conditions (to the maximum extent possible) any issued permit as may be necessary to minimize harm to such landmark.

In addition to Appendix C, impacts were also evaluated in accordance with the Advisory Council on Historic Preservation's regulations implementing §106 of the National Historic Preservation Act (36 CFR Part 800, *Protection of Historic Properties*), which are used by the Corps and Cooperating Agencies (FTA, FRA, FHWA and EPA). Accordingly, impacts to cultural resources are identified and evaluated by (1) determining the APE; (2) identifying cultural resources present in the APE that are either listed in or eligible to be listed in the National Register; (3) applying the criteria of adverse effect to affected eligible cultural resources; and (4) identifying ways to avoid, minimize or mitigate adverse effects as outlined in 36 CFR 800.6 (Resolution of Adverse Effects).

In addition to the requirements of the NHPA, all historic properties are subject to consideration under the National Environmental Policy Act (33 CFR Part 325, Appendix B), and the Corps' public interest review requirements contained in 33 CFR 320.4.

Mitigation measures include avoidance, minimization, data recovery, photographic recordation and treatment plans and these measures are discussed below. The documentation for any of these mitigation measures must provide evidence that consultation has been completed with the SHPO, concerned Indian Tribes and individuals with knowledge of affected resources. Further, mitigation measures must consider the comments of these persons on the measure(s) under consideration. Actions that the parties agree upon to resolve adverse effects will then be detailed in a Memorandum of Agreement (MOA) or PA, which is a legally binding agreement among the federal agency, the SHPO and/or Tribal Historic Preservation Officer(s), and the Advisory Council on Historic Preservation. The other consulting parties may also be invited to sign the document. Once the agreement is signed by all appropriate parties and the agreement is filed with the Advisory Council on Historic Preservation, the Section 106 process is completed. The agency's Section 106 responsibilities are fulfilled when the agreement's stipulations are implemented.

4.8.5.1 Avoidance

Avoidance is the preferred response when adverse effect is determined. Adverse effects can only be avoided for the No-Build Alternative, which does not meet the project purpose. Neither of the Build

Alternatives can avoid direct impacts to archaeological and above-ground resources. Impact to archaeological sites can be avoided through burial of the resource although this option has limited applicability. Avoiding indirect impacts resulting from noise and visual intrusions may be addressed for historic resources through design modification in some locations.

4.8.5.2 Minimization

Minimization of impact to historic properties or archaeological resources would be focused on reducing the extent of ground disturbance, establishing vegetated buffers, and designing noise barriers and sound insulation to be compatible with the historic setting.

The Adverse Effects documentation for an individual archaeological site, historic property, or district has to describe the option(s) selected to minimize impact. The Adverse Effect document also has to contain a discussion about the direct/indirect effects of the option on other archaeological sites, districts, and/or historic properties in the option's APE. In all cases, the archaeologists and historians will have to clearly document the horizontal and vertical boundaries of the archaeological site, historic property, or district in question as part of the Adverse Effects documentation.

4.8.5.3 Mitigation

The proposed project likely would result in unavoidable impacts to significant cultural resources that cannot be addressed through avoidance or minimization. Mitigation through data recovery and other approaches discussed below may include more than one action. The Adverse Effects documents prepared in support of the PA will outline the mitigation approaches that will be taken for each historic property. The Adverse Effects documents are commonly referred to as Data Recovery Plans (DRP) for archaeology and Treatment Plans for above-ground historic properties. The plans would be developed after the LEDPA is determined and all stages of intensive (locational) survey and, as needed, evaluative testing are completed and the results of the investigations evaluated by the applicable review agencies.

Specific mitigation commitments for cultural resources will be informed by additional, more detailed archeological and historic survey fieldwork and additional design detail for the preferred alternative and consultation with the tribes in the case of traditional cultural properties. In general, the types of mitigation measures that will be considered for above-ground historic resources include engineering methods that reduce noise generation or vibration, and visual barriers that help to minimize aesthetic impacts. For unavoidable adverse impacts, mitigation through data recovery, treatment plans, archival photographic documentation, architectural and barrier sound insulation or other approaches will be considered.

Historic Resources

Mitigation responses for historic resources are often impact specific. Table 4.8-22 lists the mitigation approaches that might be used to mitigate adverse effects resulting from specific project actions. As will be noted, these various mitigation options are directed to maintaining the historic character of both buildings and settings and maintaining the integrity of existing buildings.

Impacts to above-ground resources may be successfully reduced or eliminated by incorporating specific engineering methods that reduce noise generation or vibration, and through use of visual barriers that help to minimize aesthetic impacts. The following sections describe mitigation measures designed to avoid impacts to above-ground resources.

Table 4.8-22 Historic Properties Mitigation Approaches

Project Action	Mitigation Response
General (applicable to multiple actions)	Historic archival documentation
	Interpretive signs
Construction	Preconstruction inspection of building foundations and construction monitoring of building foundations
	Site specific design to be compatible with historic character in and adjacent to historic properties including districts and NHLs
Noise (including Vibration)	Preconstruction noise monitoring and early construction monitoring for impacts to specific resources with natural quiet as an element of setting
	Insulation
	Noise walls
	During construction, rubber ballast mats (or equivalent) or moveable point frog turnouts (or equivalent)
Traffic/Access	Sensitive design of access changes and turnarounds
	Traffic calming (particular to Easton)
Visual	Vegetation: minimize clearing within or adjacent to historic properties; use screen planting and landscaping to lessen visual impacts
	Lighting: within and adjacent to historic properties, minimize number of poles, paint poles non-contrast colors, use directed lights
	Built elements: use non-contrast paints on fence, roadway equipment, signal bungalows; locate signs and fixtures in a sensitive manner within and adjacent to historic properties
	Granite curbing: match roadway and sidewalk curbing to existing, granite curbing

Vibration Dampening

Vibration dampening can be an effective means or reducing or eliminating potential impacts to structures adjacent to active rail lines. Vibration dampening may be achieved by use of subgrade and ballast materials selected for reduced transmissions of vibration. Existing rail beds will be replaced with materials meeting the MBTA's standards for vibration transmission. If additional ballast treatment is necessary to avoid adverse impacts, ballast mats may be used. Ballast mats are a layer of rubber placed between the track and ballast to further reduce vibration. All bridges along the rail corridor will be reconstructed to include the use of ballasted decks containing a layer of crushed stone to absorb vibration and reduce noise generation. Specific mitigation measures used along the project corridor will be selected based on final design and the results of the historic properties impact assessment, as described in the PA (Appendix 4.8-A).

Noise Barriers

Noise barriers are an effective means of reducing the potential impacts created by new and expanded transportation corridors. In cases where trains may be passing close to historic structures or districts, this engineering solution may provide a means to reduce potential impacts from increased noise.

Visual Screening

The project has the potential to alter the settings of certain historic resources and historic districts where new stations, parking or at-grade crossings are proposed. While the original construction of the

Old Colony Railroad in the 1840s may have "fit in" with the aesthetic nature of the communities, the reactivation of the rail line using modern materials and safety standards and faster engines and larger passenger cars may result in undesirable changes in the visual environment. Screening certain structures and safety and signal equipment may mitigate these impacts. Potential screening techniques include the combination of wooden and opaque fencing with landscape plantings.

Unnecessary clear-cutting of trees and vegetation along the railroad right-of-way that could have an adverse visual impact on historic resources will be avoided and existing trees and vegetative screening will be retained to buffer visually historic properties from the rail line to the extent feasible and with due regard for public safety, operational requirements, cost, and maintenance considerations.

Project plans will include internal landscaped areas at station parking lots which are located within or which are visible from historic resources. In an adjacent to historic districts or individual resources, equipment including traffic signals and controller cabinets, street lights, street furniture, and railroad signal equipment housings will be dark colored to reduce the visual impact of this equipment. Traffic signals and street lights will be ornamental type in accordance with the towns' preferences to the extent reasonably possible.

These methods, when used in combination with other mitigation measures such as noise barriers, may successfully reduce and mitigate some potential visual impacts to historic properties associated with the South Coast Rail project.

Use of Compatible Materials within Historic Districts

To the extent practicable, the project will use materials compatible in color, texture and form to minimize adverse visual impacts to historic structures and districts.

A review of current conditions and materials will be undertaken prior to completion of environmental review and when more design information is available in order to ensure the use of compatible materials in the vicinity of historic properties. All repair, rehabilitation, or modification of historic properties, including sound insulation treatments for mitigation of noise impacts, will be performed in accordance with the U.S. Secretary of the Interior's "Standards for the Treatment of Historic Properties, including Guidelines for Preserving, Rehabilitating, Restoring, and Reconstructing Historic Buildings."

Construction Staging and Methods

Construction staging and storage areas shall be located in protected areas outside historic districts and resources wherever possible, and in as unobtrusive a location as possible within historic districts or resources if alternative locations are infeasible. Where historic resources used as residences are within 50 feet of a staging area, a temporary solid wood fence, 6 feet high, will be used a visual screen between the residence(s) and the staging area.

Archaeological Resources

Impacts to archaeological resources will occur when archaeological sites are disturbed during construction. The South Coast Rail alternatives have been designed to minimize potential impacts to below-ground resources by maximizing reuse of the existing rail bed and right-of-way.

Unavoidable impacts to archaeological resources will be identified by further analysis of specific construction sites and appropriate, avoidance, minimization or mitigation selected during the Section

106 consultation process. Where impacts to archaeological resources are unavoidable, MassDOT will proceed with subsequent detailed site investigations and/or data recovery as may be stipulated in the PA developed for this project.

The mitigation approaches for archaeological sites tend to focus on data recovery: the acquisition of additional site-specific data usually consisting of more feature information and/or artifacts. There are other alternatives, referred to as Creative or Alternative Mitigation Strategies that can be explored once the impacts to archaeological sites are known. Such creative approaches may include oral histories (for historical archaeological sites), whole site excavation, laboratory work to the exclusion of additional excavation, and non-traditional reporting. Data recovery and these other options are briefly explored below.

Data recovery usually involves block excavations or the complete excavation of specific features such as privies or wells. These excavations are designed to augment and expand upon prior work to reach a cumulative percentage of site area ranging from five to ten percent. Except in certain instances, the only area of the site that will be subjected to data recovery excavation is that within the direct impact area.

The other alternatives that will be considered are non-excavation strategies and some of these may actually be used in tandem with excavation. For historical archaeological sites, the acquisition of information about site function through oral histories is particularly effective for sites that may represent particular industrial or commercial enterprises, or that represent the homes of persons from particular religious or cultural backgrounds. Laboratory analyses of particular artifact types or artifact collections have also been used as an alternative mitigation measure to additional excavation. This has been particularly effective when large collections of artifacts acquired by avocational archaeologists are available for analysis by professionals. Finally, the use of non-traditional reporting is proving to be exceptionally welcome by the public and a critical deliverable in all data recovery efforts. Non-traditional reporting includes, for example, educational web sites; the creation of teaching plans and supporting materials; video/DVD production showing the range and types of cultural resources in areas or other appropriate stories; and the production of popular books, pamphlets, or brochures for use in public outreach.

4.8.6 Regulatory Compliance

This section outlines the regulatory compliance requirements for cultural resources. These resources are regulated at the federal and state levels, and are always considered in NEPA and MEPA analyses. At the federal level, Section 106 of the National Historic Preservation Act of 1966 as amended (36 CFR 800) provides the regulatory framework for the compliance guidelines for the identification and evaluation of cultural resources. At the state level, Massachusetts General Laws Chapter 9, Chapter 254, Sections 26-27C, as amended; and 950 CMR 71.00, 950 CMR 70.00 provides the regulatory framework for the state compliance guidelines, under the jurisdiction of the SHPO. Other relevant legislation and regulations include the National Environmental Policy Act of 1969, as amended;[5] Executive Order 11593, "Protection and Enhancement of Cultural Environment;"[6] Sections 106 and 110 of the National Historic Preservation Act of 1966, as amended,[7] implementing regulation 36 CFR 800, as revised January 2001;

[5] National Environmental Policy Act of 1969, as amended (42 U.S.C. $$ 4321-4347).

[6] Executive Order No. 11593. "Protection and Enhancement of the Cultural Environment," CFR 154 (1971) reprinted in 16 U.S.C.$470 note.

[7] Advisory Council on Historic Preservation. Sections 106 and 110 of the National Historic Preservation Act of 1966 (January 2001) 36 CFR 800.

and, the Procedures for the Protection of Historic Properties (Appendix C) at 33 CFR Part 325 - Processing of Department of the Army Permits.

The historic and archaeological resources intensive surveys for the South Coast Rail project were undertaken in accordance with the Secretary of the Interior's *Standards and Guidelines for Identification* (48 FR 44720-23), the Massachusetts Historical Commission (MHC) standards and guidelines set forth in *Public Planning and Environmental Review: Archaeology and Historic Preservation* (MHC 1985), and the MHC historic resources survey standards. The survey complies with the standards of the MHC, state archaeologist's permit regulations (950 CMR 70), the Secretary of the Interior's *Standards and Guidelines for Identification* (48 FR 44720-23), The Standards of the Massachusetts State Register of Historic Places (State Register), and the National Park Service (NPS) guidelines for assessing eligibility for listing in the National Register, specifically *National Register Bulletin 15: How to Apply the National Register Criteria for Evaluation*. While the surveys conducted to date have informed the impact analysis, additional surveys would be conducted as necessary when more design information is available to further and more specifically assess potential impacts to cultural resources.

4.8.6.1 National Historic Preservation Act

Section 106 of the National Historic Preservation Act of 1966, as amended,[8] seeks to accommodate historic preservation concerns with the needs of federal undertakings through consultation among agency officials and other parties with an interest in the effects of the undertaking on historic properties. The goal of the consultation is to identify historic properties that might be potentially impacted by the undertaking, assess its effects, and seek ways to avoid, minimize, or mitigate any adverse effects on historic properties.[9]

The Army Corps, as the lead federal agency for the South Coast Rail project, has compliance responsibilities regarding cultural resources under the Procedures for the Protection of Historic Properties (Appendix C) at 33 CFR Part 325 - Processing of Department of the Army Permits, Section 106 of the National Historic Preservation Act (NHPA) as amended, the regulations of the Advisory Council on Historic Preservation (Council) at 36 CFR 800, and the National Environmental Policy Act (NEPA).

4.8.6.2 Massachusetts General Laws, Chapter 9

MassDOT serves as the lead state agency and is responsible for identifying and evaluating properties through archaeological and historic architectural surveys in accordance with MGL Ch. 9 Sections 26-27C, as amended; 950 CMR 71.00, 950 CMR 70.00 and the Massachusetts Environmental Policy Act (MEPA). MGL Chapter 9 Section 26-27C stipulates that any project that requires funding, licenses or permits from any state agency must be reviewed by the SHPO.

4.9 AIR QUALITY

4.9.1 Introduction

This chapter assesses the effects of the alternatives on future air quality conditions at regional (mesoscale) and local (microscale) levels. Section 4.9.2 identifies the air quality analysis methodology. Section 4.9.3 describes the air quality results for the alternatives and their elements. Section 4.9.4 reviews the potential temporary construction impacts and related mitigation. Section 4.9.5 presents a summary of the impacts by each alternative and Section 4.9.6 discusses regulatory compliance. Transportation-related mitigation measures are described in Chapter 4.1, *Transportation*.

The Certificate on the ENF issued by the Secretary of the Executive Office of EEA on April 3, 2009[1] identified the following aspects to be addressed in the evaluation of air quality impacts:

- A mesoscale analysis of volatile organic compounds (VOCs), nitrogen oxides (NO_X), carbon dioxide (CO_2), carbon monoxide (CO), and particulate matter (PM) associated with the project alternatives.
- A microscale analysis of CO, PM_{10}, and $PM_{2.5}$ for hotspot locations that includes vehicles and locomotives around stations and layover facilities where idling emissions will occur.
- An analysis of Greenhouse Gas (GHG) (CO_2) emissions in accordance with MEPA's policy.
- Evaluation in the GHG analysis of electric and diesel fuel options for the trains.
- Evaluation in the GHG analysis of cumulative impacts by alternatives as well as buildings comparing the current state building codes to proposed building with mitigation measures.
- Discussion and consideration in the GHG analysis of recommendations by the Massachusetts Zero Net Energy Building Task Force.
- An investigation as part of the GHG analysis of renewable energy sources and commitment to appropriate LEED and Energy Star elements.
- Evaluation in the GHG analysis of cumulative impacts and the potential effects on freight traffic.
- Commitments in the GHG analysis to using train engine plug-ins and electric block heaters at layover facilities and a discussion of how the project will meet federal locomotive emission standards.

The Secretary's Certificate on the DEIS/DEIR, issued on June 29, 2011, required further analysis or discussion on several aspects of air quality impacts in the FEIS/FEIR. The Certificate states that the FEIS/FEIR should:

[1] Massachusetts Executive Office of Energy and Environmental Affairs. Certificate of the Secretary of Energy and Environmental Affairs on the Environmental Notification Form. April 3, 2009.

- Include an evaluation of alternative fuels for the enhanced bus and feeder bus services, and commit to use of hybrid and/or other fuels to minimize emission of air pollutants to the maximum extent possible.
- Reiterate commitments to construction-related mitigation measures.
- Identify design and operational features that MassDOT will commit to in order to reduce GHG emissions [greenhouse gas]; including measures to promote GHG reductions associated with transit-oriented development facilities and other induced growth.
- Consult with the Mass Department of Energy Resources (DOER), Division of Green Communities, for assistance in developing a joint approach to promote energy efficiency and GHG reduction in SCR communities.
- Provide an update on consultations with DOER and utility companies on ways that communities can use incentives to mitigate GHG emissions from induced growth.
- Include an outline of the proposed GHG mitigation plan.
- Include the results of revised analysis of induced growth impacts on traffic and air quality.
- Describe in detail specific commitments to contribute to VMT (vehicle miles travelled) and GHG reductions through the feeder bus system.
- Document how the project will comply with MassDEP air quality regulations.

4.9.1.1 Resource Definition

Air quality refers to the ambient concentration of air pollutants in the atmosphere. Air pollutants are substances (naturally occurring or human-generated) that can have adverse effects on human health and/or natural resources. Of special concern are the respiratory effects of the pollutants and their potential toxic effects, as described in Section 4.9.1.3 below.

4.9.1.2 Regulatory Context

The USEPA is responsible for establishing the National Ambient Air Quality Standards (NAAQS), enforcing the Clean Air Act (CAA), and regulating transportation-related emission sources, such as aircraft, ships, and certain types of locomotives. The USEPA also establishes vehicular emission standards.

Clean Air Act and General Conformity Rule

The CAA defines nonattainment areas as geographic regions designated as not meeting one or more of the NAAQS. It requires that a state implementation plan (SIP) be prepared for each nonattainment area, and a maintenance plan be prepared for each former nonattainment area that subsequently demonstrated compliance with the standards. A SIP is a compilation of a state's air quality control plans and rules, approved by USEPA. Section 176(c) of the CAA provides that federal agencies cannot engage, support, or provide financial assistance for licensing, permitting, or approving any project unless the project conforms to the applicable SIP. The state and USEPAs' goals are to eliminate or reduce the severity and number of violations of the NAAQS and to achieve expeditious attainment of these standards.

Pursuant to CAA Section 176(c) requirements, USEPA promulgated Title 40 of the Code of Federal Regulations Part 51 (40 CFR 51) Subpart W and 40 CFR Part 93, Subpart B, "Determining Conformity of General Federal Actions to State or Federal Implementation Plans" (see 58 Federal Register [FR] 63214, [November 30, 1993], as amended, 75 FR 17253 [April 5, 2010]). These regulations, commonly referred to as the General Conformity Rule, apply to all federal actions except for those federal actions which are excluded from review (e.g., stationary source emissions) or related to transportation plans, programs, and projects under Title 23 U.S. Code or the Federal Transit Act, which are subject to Transportation Conformity. The General Conformity Rule applies to all federal actions not addressed by the Transportation Conformity Rule. The South Coast Rail project is not expected to involve funding or approvals from the Federal Highway Administration or the Federal Transit Administration. The Rapid Bus Alternative, which may have required approvals from the Federal Highway Administration associated with changes to the Federal Highway System or other approvals is no longer under consideration. The primary federal approvals required for the project are the NEPA Record of Decision and permits from the U.S. Army Corps of Engineers (the Corps). Therefore, Transportation Conformity does not apply and the applicable conformity regulation is the General Conformity Rule.

The General Conformity Rule is used to determine if federal actions meet the requirements of the CAA and the applicable SIP by ensuring that air emissions related to the action do not:

- Cause or contribute to new violations of a NAAQS.
- Increase the frequency or severity of any existing violation of a NAAQS.
- Delay timely attainment of a NAAQS or interim emission reduction.

A conformity determination under the General Conformity Rule is required if the federal agency determines: the action will occur in a nonattainment or maintenance area; that one or more specific exemptions do not apply to the action; the action is not included in the federal agency's "presumed to conform" list; the emissions from the proposed action are not within the approved emissions budget for an applicable facility; and the total direct and indirect emissions of a pollutant (or its precursors), are at or above the de minimis levels established in the General Conformity regulations (75 FR 17255).

The General Conformity rule defines direct emissions as "caused or initiated by the Federal action and originate in a nonattainment or maintenance area and occur at the same time and place as the action and are reasonably foreseeable." Indirect emissions are defined as emissions of a criteria pollutant or its precursors:

- That are caused or initiated by the Federal action and originate in the same nonattainment or maintenance area but occur at a different time or place as the action;
- That are reasonably foreseeable;
- That the agency can practically control; and
- For which the agency has continuing program responsibility.

For the purposes of this definition of indirect emissions, even if a Federal licensing, rulemaking or other approving action is a required initial step for a subsequent activity that causes emissions, such initial steps do not mean that a Federal agency can practically control any resulting emissions (.40 CFR 93.152).

For the South Coast Rail project, the Corps' Section 404 permit decision may cause temporary construction emissions that would need to be considered under General Conformity. However, the long-term locomotive emissions under the Stoughton or Whittenton Diesel Alternatives would not be subject to General Conformity requirements because the Corps would have no way of controlling the emissions nor any continuing program responsibility over commuter rail operations.

4.9.1.3 Pollutants of Concern and Attainment Status

Carbon Monoxide

CO is a colorless and odorless gas that is a product of incomplete combustion. Carbon monoxide is absorbed by the lungs and reacts with hemoglobin to reduce the oxygen carrying capacity of the blood. At low concentrations, CO has been shown to aggravate the symptoms of cardiovascular disease. It can cause headaches and nausea and, at sustained high concentration levels, can lead to coma and death.

Proposed projects that are located in CO non-attainment or maintenance attainment areas are required to evaluate their impact on CO concentrations and the NAAQS. The alternatives under consideration are located in Fall River, New Bedford, Taunton/East Taunton, Raynham, and Easton/North Easton. These cities along the various alternative corridors are in attainment of air quality standards for CO. A microscale CO analysis was not required under General Conformity because the project is not in a nonattainment or maintenance area, but was conducted for NEPA purposes to better understand the potential effects of the alternatives on air quality.

Particulate Matter

Particulate matter is made up of small solid particles and liquid droplets. PM_{10} refers to particulate matter with a nominal aerodynamic diameter of 10 micrometers or less, and $PM_{2.5}$ refers to particulate matter with an aerodynamic diameter of 2.5 micrometers or less. Particulates can enter the body through the respiratory system. Particulates over 10 micrometers in size are generally captured in the nose and throat and are readily expelled from the body. Particles smaller than 10 micrometers, and especially particles smaller than 2.5 micrometers, can reach the air ducts (bronchi) and the air sacs (alveoli) in the lungs. Particulates are associated with increased incidence of respiratory diseases, cardiopulmonary disease, and cancer. The cities along the alternatives corridors are in attainment of PM standards. A microscale PM analysis was not required under General Conformity because the project is not in a nonattainment or maintenance area, but was conducted for NEPA purposes to better understand the potential effects of the alternatives on air quality.

Ozone

Ozone is a strong oxidizer and an irritant that affects the lung tissues and respiratory functions. Exposure to ozone can impair the ability to perform physical exercise, can result in symptoms such as tightness in the chest, coughing, and wheezing, and can ultimately result in asthma, bronchitis, and emphysema.

Massachusetts has been determined to be a non-attainment area, statewide, for ozone. The Commonwealth has been divided into two non-attainment areas, Eastern and Western Massachusetts. On June 15, 2005, the USEPA revoked the 1-hour ozone standard for most areas in the country. The South Coast Rail alternatives are located in the eastern Massachusetts 8-hour ozone non-attainment area, which has been classified as "Moderate."

Volatile Organic Compounds

VOCs are a general class of compounds containing hydrogen and carbon and are a precursor to the formation of the pollutant ozone. While concentrations of VOCs in the atmosphere are not generally measured, ground-level ozone is measured and used to assess potential health effects. Emissions of VOCs and NO_X react in the presence of heat and sunlight to form ozone in the atmosphere. Accordingly, ozone is regulated as a regional pollutant and not assessed as part of microscale air quality analysis.

Nitrogen Oxides

When combustion temperatures are extremely high, as in automobile engines, atmospheric nitrogen gas may combine with oxygen gas to form various oxides of nitrogen. Of these, nitric oxide (NO) and nitrogen dioxide (NO_2) are the most significant air pollutants. This group of pollutants is generally referred to as nitrogen oxides or NO_X. Nitric oxide is relatively harmless to humans but quickly converts to NO_2. Nitrogen dioxide has been found to be a lung irritant and can lead to respiratory illnesses. Nitrogen oxides, along with VOCs, are also precursors to ozone formation.

Carbon Dioxide

Greenhouse gases (GHG) are essential to maintaining the temperature of the Earth; without them the planet would be so cold as to be uninhabitable. The earth's climate is predicted to change over time, in part because human activities are altering the chemical composition of the atmosphere through the buildup of GHGs. Climate change is having and will continue to have wide ranging impacts on water, energy, transportation, agriculture, ecosystems, and health.[2] While there are other GHGs, carbon dioxide (CO_2) is the predominant contributor to climate change, and emissions can be calculated for CO_2 with readily accessible data.

The EEA issued a policy and protocol for evaluating greenhouse gas (GHG) emissions from proposed projects with particular emphasis on CO_2 emissions.[3] This policy requires that EIR projects quantify greenhouse gas emissions generated by the project and identify measures to reduce or minimize these impacts.

To date, no national standards or thresholds for greenhouse gas emissions applicable to transit projects have been established. USEPA has identified certain greenhouse gases as pollutants under the Clean Air Act and regulatory actions to date have included emissions standards for motor vehicles, fuel standards, and carbon pollution standards for new power plants, among other actions.[4]

On February 18, 2010, the CEQ issued “Draft NEPA Guidance on Consideration of the Effects of Climate Change and Greenhouse Gas Emissions” for public review and comment.[5] The Draft Guidance addresses when and how to evaluate both the greenhouse gas emissions from proposed actions and the potential impacts of climate change on proposed actions. The Draft Guidance recommends 25,000 metric tons of direct CO_2-equivelent emissions per year as an indicator for when a quantitative greenhouse gas emissions analysis may be appropriate to include in NEPA documents. As of June 2013, the Draft Guidance has not been finalized.

4.9.1.4 Air Quality Standards

The USEPA has set the primary NAAQS to protect public health. Secondary standards set limits to protect public welfare, including protection against visibility impairment, damage to animals, crops, vegetation, and buildings. Table 4.9-1 outlines the primary and secondary NAAQS for all of the criteria pollutants. The predominant source of pollution anticipated from the alternatives under consideration is emissions from project-related motor vehicle traffic. CO and PM are directly emitted by motor vehicles. CO and PM concentrations can be estimated by computer modeling, which can then be compared to the NAAQS.

Table 4.9-1 National Ambient Air Quality Standards

Pollutant		Primary/ Secondary	Averaging Time	Level	Form
Carbon Monoxide		primary	8-hour	9 ppm	Not to be exceeded more than once per year
			1-hour	35 ppm	
Lead		primary and secondary	Rolling 3 month average	0.15 μg/m^3	Not to be exceeded
Nitrogen Dioxide		primary	1-hour	100 ppb	98th percentile, averaged over 3 years
		primary and secondary	Annual	53 ppb	Annual Mean
Ozone		primary and secondary	8-hour	0.075 ppm	Annual fourth-highest daily maximum 8-hr concentration, averaged over 3 years
Particle Pollution	$PM_{2.5}$	primary	Annual	12 μg/m^3	annual mean, averaged over 3 years
		secondary	Annual	15 μg/m^3	annual mean, averaged over 3 years
		primary and secondary	24-hour	35 μg/m^3	98th percentile, averaged over 3 years
	PM_{10}	primary and secondary	24-hour	150 μg/m^3	Not to be exceeded more than once per year on average over 3 years
Sulfur Dioxide		primary	1-hour	75 ppb	99th percentile of 1-hour daily maximum concentrations, averaged over 3 years
		secondary	3-hour	0.5 ppm	Not to be exceeded more than once per year

4.9.2 Methodology

4.9.2.1 Mobile Source Air Quality Modeling Methodology

The USEPA and DEP have established guidelines that define the modeling and review criteria for local and regional air quality analyses prepared pursuant to the MEPA process. These guidelines require that a proposed project determine the change in project related vehicle emissions. If the VOC and emissions from the Build Alternatives are greater than the No-Build Alternative, then a proposed project should include all reasonable and feasible emission reduction mitigation measures. Massachusetts has incorporated this criterion into its SIP.

The USEPA and DEP guidelines require that the air quality study utilize traffic and emissions data for existing and future (No-Build and Build) conditions. The traffic and emissions data are incorporated into the USEPA air quality models and modeling procedures to generate emissions estimates that demonstrate whether or not a proposed project will have air quality impacts.

The air quality study for the project evaluated several conditions, including the 2008 existing conditions, the 2016 and 2030/2035 No-Build Alternative, and the Stoughton and Whittenton Alternatives (electric and diesel variants). The No-Build Alternative (2030 and 2035) included regional background traffic growth and planned roadway improvements. The Build Alternatives include the anticipated future changes in travel demand associated with each alternative. The year 2016 was analyzed as it represented the estimated date of completion at the time the DEIS/DEIR studies were undertaken. In addition, the year 2030 was selected as the future year of analysis for the microscale air quality assessment to be consistent with the statewide model and for consistency with the regional long-range transportation plan at the time the DEIS/DEIR was prepared. For this FEIS/FEIR, the regional (mesoscale) air quality analyses were updated for a 2035 analysis year and updated ridership projections prepared by CTPS (see Chapter 4.1, *Transportation*). Future alternative-related emission calculations are based upon changes in traffic and emission factor data. The traffic data include traffic volumes, vehicle-miles-of-travel, roadway operations, and physical roadway improvements. The emission factor data include emission reduction programs, years of analysis, and roadway speeds.

The microscale and mesoscale analyses developed traffic (volumes and speeds) and emission factor data for the No-Build and Build Alternatives. These data were incorporated into air quality models to demonstrate that the proposed South Coast Rail alternatives will meet the CAAA and SIP criteria. The mesoscale analysis evaluated the regional air quality impacts (VOCs, NO_x, CO_2, CO, and PM emissions) from the alternatives under consideration by determining the change in total ozone precursor emissions (volatile organic compounds and nitrogen oxides) for the existing and future conditions within the study area. The microscale analysis calculated the CO and PM concentrations for the same conditions at congested intersections near the project stations.

The NAAQS for CO, PM, ozone, and other criteria pollutants have been set by the USEPA to protect the public health. The Commonwealth of Massachusetts has adopted the same standards as those set by the USEPA. The predominant sources of air pollution anticipated from the alternatives include emissions of CO, PM, NO_x, and VOCs from locomotive engines and from motor vehicles traveling to and from the stations. Carbon monoxide emissions are emitted predominantly by motor vehicles. PM emissions are emitted by motor vehicles and diesel engines. The impacts of CO and PM are estimated in the microscale analysis by modeling CO and PM concentrations at congested locations, typically intersections, and comparing the results to the NAAQS. Locomotives and vehicles do not directly emit ozone, which is formed through a complex chemical process that occurs when ozone precursor emissions (NO_x and VOCs) react in the presence of sunlight and heat. The ozone impacts due to the proposed project were evaluated by assessing changes in ozone precursor emissions in the mesoscale analysis and comparing the results to the CAAA and conformity criteria.

Microscale Analysis Methodology

The microscale analysis evaluated the CO and PM concentrations at congested intersections in the study area. The intersections selected for microscale air quality modeling were selected based upon the

procedures outlined by the USEPA and as referenced in the DEP guidelines.[6] These procedures require that the intersections be ranked by their level-of-service (LOS) and their total traffic volumes, and that the air quality analysis model the highest three intersections in each ranking. In addition, study intersections were added that would be impacted by station-related traffic and represent those that are in the vicinity of the proposed station sites. Intersections in the study area were ranked based on traffic volumes and level of service. The following intersections were selected for analysis because they were the most congested intersections within the vicinity of each station:

- Taunton Depot, East Taunton: Route 140 at the Route 24 Southbound Ramps
- Easton Village, Easton: Route 138 at Main Street
- Fall River Depot, Fall River: North Davol Street and South Davol Street at President Avenue
- Freetown Station, Freetown: South Main Street at Route 24 Northbound Ramps
- King's Highway, New Bedford: Church Street at Tarkiln Road
- North Easton, North Easton: Route 138 at Main Street
- Raynham Park, Raynham: Route 138 at Foundry Street/Route 106
- Dean Street, Taunton: Route 44 at Longmeadow Road
- Taunton Depot, Taunton: Route 140 at the Route 24 Northbound without Slip Ramp
- Dana Street, Taunton: Washington Street at Tremont Street
- Whale's Tooth, New Bedford: Union Street at McArthur at Route 18 at State Pier
- Relocated Stoughton Station, Stoughton: Brock Street/Kinsley Street at Washington Street

The impacts of the alternatives on the nearest residences were assessed for CO and PM emissions to determine whether the emissions are below (in compliance with) the required standards.

The microscale analysis calculated maximum 1-hour and 8-hour CO concentrations, the 24-hour and annual $PM_{2.5}$ concentrations, and the 24-hour PM_{10} concentrations. The USEPA's computer model CAL3QHC[7] was used to predict CO and PM concentrations at receptor locations for each intersection. These receptor locations were selected since they are located where the public has access and is expected to be for periods of time. Receptors were placed at the edge of the roadway, but not closer than 10 feet (3 meters) from the nearest travel lane, so that they were not within the roadway mixing cell. The results calculated at these receptor locations represent the highest concentrations at each intersection. Receptor locations farther away from the intersections will have lower concentrations because of the CO and PM dispersion characteristics. The receptor locations that are along the major

[6] Guidelines For Modeling Carbon Monoxide From Roadway Intersection, U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards, Technical Support Division; Research Triangle Park, NC; EPA-454/R-92-005; November 1992.

[7] User's Guide to CAL3QHC Version 2.0: A Modeling Methodology for Predicting Pollutant Concentrations Near Roadway Intersections, US Environmental Protection Agency, Office of Air Quality Planning and Standards, Technical Support Division; Research Triangle Park, NC; EPA-454/R-92-006; November 1992.

roadways in the study area are also expected to have lower CO and PM concentrations than intersection receptors. The reason for this is that emission rates for vehicles traveling along these roadways are much lower than the emission rates for vehicles queuing at intersections, with stop-and-go traffic.

Subsequent to the DEIS/DEIR, updated microscale analyses were performed to assess the effects of relocating the Stoughton Station. All other microscale analyses remain the same as presented in the DEIS/DEIR—given that the results show concentrations well below the NAAQS, updating the analyses to account for the latest ridership and operating plan would not change the conclusions regarding the effects of the alternatives on air quality at the local level.

The potential for traffic changes as a result of the selection of the Dana Street Station in Taunton to replace the Downtown Taunton Station were evaluated and it was concluded that an updated microscale analysis was not warranted. The vehicle trips related to the proposed Dana Street Station as based on ridership modeling are less than half of the previous estimates for the Downtown Taunton Station. When compared to the Downtown Taunton Station analyzed in the DEIS/DEIR, this removes a substantial amount of project-related vehicular traffic from the downtown Taunton area and reduces project impacts related to the station. Although it is projected by CTPS that a higher percentage of riders would drive to a station on Dana Street (69 percent of riders) when compared to a station in Downtown Taunton (44 percent), the overall number of vehicle trips to and from the Dana Street Station is still substantially lower compared to the Downtown Taunton station location. Therefore, the results of the DEIS/DEIR air quality impact analysis for the Washington Street at Tremont Street intersection are conservatively high. The DEIS/DEIR analysis indicated that these impacts would not be significant and further impact analysis specific to the Dana Street Station is therefore not necessary.

Background Concentrations

The 1-hour pollutant concentrations were calculated directly using the USEPA computer model, with evening peak hour traffic and emissions data.

CO Background and Persistence Factors—The 8-hour CO concentrations were derived by applying a persistence factor of 0.70 to the 1-hour CO concentrations. The concentrations are expressed in parts per million (ppm) and include a 1-hour and 8-hour background concentration of 3.0 ppm and 2.1 ppm respectively. The CO persistence factor and background concentration are based on USEPA's suggested factors. The 1-hour NAAQS for CO is 35 ppm. The emissions presented represent the highest emissions experienced at each intersection for each alternative. The air quality analysis assumes that if these intersections meet the NAAQS, then all other intersections, regardless of alternative, which would have lower volumes and better levels of service, can be assumed to also meet the NAAQS. The remaining intersections are included in Appendix 4.9-A.

PM_{10} Background and Persistence Factors—The microscale analysis calculated the 24-hour PM_{10} concentrations for the No-Build Alternative and the Build Alternatives. The 1-Hour PM_{10} concentrations were calculated directly using the USEPA's CAL3QHC model, with evening peak hour traffic and emission data. The 24-hour PM_{10} concentrations were calculated by applying the USEPA persistence factor of 0.40 to the 1-hour concentrations. The concentrations are expressed in micrograms per cubic meter ($\mu g/m^3$) and include a 24-hour background concentration of 45.7 ug/m^3, which was based on DEP air quality monitoring data. The background concentrations are conservative because they were calculated from

the DEP's annual monitoring report[8] at DEP's Boston area (Kenmore Station) permanent monitoring station. The 24-hour NAAQS for PM_{10} is 150.0 μg/m^3.

$PM_{2.5}$ Background and Persistence Factors—The microscale analysis calculated the 24-hour and annual $PM_{2.5}$ concentrations for the No-Build Alternative and the Build Alternatives. The 1-hour $PM_{2.5}$ concentrations were calculated directly using the USEPA's CAL3QHC model, with evening peak hour traffic and emission data. The 24-hour $PM_{2.5}$ concentrations were calculated by applying the USEPA persistence factor of 0.40 to the 1-hour concentrations and 0.08 for the annual $PM_{2.5}$. The concentrations are expressed in micrograms per cubic meter (μg/m^3) and include a 24-hour background concentration of 29.7 μg/m^3, and an annual background concentration of 11.7 μg/m^3 which was based on DEP air quality monitoring data. The background concentrations were also calculated from the DEP's annual monitoring report[9] at DEP's Boston-area (Kenmore Station) permanent monitoring station. The 24-hour NAAQS for $PM_{2.5}$ is 35.0 μg/m^3 and 15.0 μg/m^3 for the annual standard.

The highest CO, $PM_{2.5}$ and PM_{10} concentration and its receptor location presented in Section 4.9.3 represent the highest concentrations for each intersection. Receptor locations located farther away from the intersection have lower concentrations because of the pollutant's dispersion characteristics. Receptor locations that are along major roadways are also expected to have lower pollutant concentrations, because the emission factors for vehicles traveling along these roadways are much lower than the emission rates for vehicles queuing at the modeled intersections. The receptor locations for each intersection are presented in Figures 4.9-1 through 4.9-7.

Emission Factors

The vehicle emission factors used in the microscale and mesoscale analysis were obtained using the USEPA's Mobile Source Emission Factor Model, MOBILE6.2,[10] which calculates emission factors from motor vehicles in grams per vehicle-mile for existing and future conditions. The emission rates calculated in this air quality study are adjusted to reflect Massachusetts-specific conditions such as the vehicle age distribution, the statewide Inspection and Maintenance (I/M) Program, and the Stage II Vapor Recovery System.[11] VOC and NO_x emission factors for the mesoscale analysis were determined using the DEP recommended temperatures for the summer (ozone) season and similarly for the microscale analysis, the CO emission factors were determined using winter (CO) season temperatures. The MOBILE6.2 input data are presented in Appendix 4.9-A. The MOBILE6.2 model was the latest USEPA-approved mobile source emissions model at the time the DEIS/DEIR was prepared and remains appropriate for assessing the effects of the alternatives in this FEIS/FEIR.

The air quality study used traffic data (volumes, delays, and speeds) developed for each analysis condition. The microscale analysis used the evening peak hour traffic conditions during the CO season (winter).

Train Emissions for Microscale Analysis—There would be no train emissions under the electric Build Alternatives, but the diesel Build Alternatives would result in additional particulate matter emissions.
